PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

5763 SMALL-INTESTINAL LENGTH: AN INTRAOPERATIVE STUDY IN OBESITY. *(E.)* Backman, L.; Hallberg, D. (Karolinska Hosp., Stockholm, Sweden). *Acta Chir. Scand.* 140(1):57-63, 1974.

Small intestine length, important because it gives an indirect determination of resorptive capacity, was measured during abdominal surgery in 56 subjects undergoing small intestine shunt for massive intractable obesity and in 32 control patients of normal weight with elective gastrointestinal surgery. Two measurements of length between the ileocecal valve and Treitz ligament were made with a common white cotton band, excluding the duodenum. The 2nd figures were always 10% shorter, the difference being independent of the lengths of the measured segments; the shortening indicated that handling and stretching of the intestine influenced the 2nd measurement due to increased contractility of the smooth muscle. Serotonin released in the intestinal wall also increased reactivity. In some cases, a 3rd measurement gave values very close to the 2nd. All measurements showed that the female small intestine was shorter than the male. In obese patients with a mean body weight of 149.7 kg for men and 137.2 kg for women, the small intestine length was significantly longer than in controls: for men, 8.24 m compared with 6.98 m in the control group (mean body weight of 69.2 kg); values for women were 7.34 m in the obese group and 6.16 m in the controls (mean body weight of 61.5 kg). Significant correlations between small intestine length and various other body parameters were also found, the highest being body surface. A statistically significant difference in small intestine length was associated with age of onset of obesity in that the small intestine was longer in subjects with onset after puberty; age *per se* was not a factor. Fat cell diameter, surface, and volume, estimated in 18 cases peroperatively, showed no significant correlation to small intestine length, and there was also no significant difference between the 2 groups regarding body weight and body height. Possible explanations for the correlation between overweight and a longer small intestine include (1) a congenitally long intestine resulting in a possible hyperplasia and (2) development of a longer small intestine secondary to an adaptive mechanism such as overfeeding (causing hypertrophy) and endocrine compensation resulting in both hyperplasia and hypertrophy. However, the measurements obtained here indicating that belated onset of obesity is associated with a longer small intestine than an earlier onset do not favor the above theories.

5764 HISTOCHEMICAL CHARACTERIZATION OF MUCINS IN THE HUMAN GASTROINTESTINAL TRACT: NORMAL RECTAL MUCOSA. *(It.)* Ravetto, C.; Volpi, G.; Di Marco, G. (Inst. Normal Hum. Anat., Univ. Modena, Italy). *Arch. Ital. Mal. App. Dig.* 37(1):49-61, 1973.

Histochemical studies were performed on goblet cells in sections made from rectal biopsies taken from women, aged 30-50 yr, with no evidence of gastrointestinal disease. None of these subjects were undergoing any treatment which would change normal gastrointestinal function in any way. Two types of mucin were found. One gave a positive reaction with stains for sulfated mucins and was found primarily in goblet cells at the bottom of crypts, but was also present in variable amounts in more superficial cells. The second type of mucin gave negative tests for sulfated mucins but reacted positively with reagents for carboxyl groups. Deacetylation with ammonia in an ethanol-water solution intensified its reactions with periodic acid-Schiff (PAS) reagent and with sialidase. Thus, this fraction consists of a mucin containing sialidase-labile sialic acid and N-acetyl-O-diacetylsialic acid which is attacked by sialidase only after deacetylation. Neither mucin reacted with hyaluronidase or chitinase, indicating that no chondroitin sulfate or hexosamines with a β-1,4-glycosidic linkage are present. Variability in the intensity of staining with PAS in the subjects examined appears to be physiological and not an indication of any manifest or latent pathological condition.

5765 THE DYNAMIC STRUCTURE OF A FLAT SMALL INTESTINAL MUCOSA STUDIED ON THE EXPLANTED RAT JEJUNUM. *(E.)* Loehry, C. A.; Grace, R. (Royal Victoria Hosp., Bournemouth, England). *Gut* 15(4): 289-293, 1974.

Small pieces of albino rat jejunum (3-4 cm long) with an intact blood supply were explanted, free mucosal surface uppermost, to the anterior abdominal wall. After 6 weeks the mucosa appeared totally flat in many areas, both histologically and under the dissecting microscope. The structure of the flattened mucosa was identical to that in celiac disease with hypertrophied intervillous ridges. A hemolytic-like change in mucosal dynamics is suggested, with primary increase in cell loss causing shortening of the villi, and a compensatory increased cell production in the crypts producing hypertrophy of the intervillous ridges to form a convoluted and flattened structure. Mitotic activity in the explanted mucosa was 510 mitosies/1000 crypt cells compared with a normal control rate of 250. Although no direct evidence of increased cell loss was seen, the histological appearance of trauma at villi tips was strongly indicative of a faster than normal rate of cell loss. Experiments with tritium-labeled thymidine demonstrated a considerably increased epithelial cell turnover with some disorganization of cell production and migration. If a hemolytic-like change in mucosal dynamics is applicable to the flat mucosa of celiac disease, increased cell loss may indicate a parallel increased loss of intracellular substances that the abnormal mucosa is unable to absorb (e.g., iron loss). In addition, each epithelial cell may be available for absorption for a shorter period, and some cells may be functionally immature at the crypt mouth. With disruption of cell production, many cells may never be fully available for absorption.

5766 SUBSURFACE CISTERNS IN MOUSE HEPATOCYTES. *(E.)* Tandler, B.; Hoppel, C. L. (Dept. Oral Biol, Med., Case Western Reserve Univ., Cleveland, Ohio). *Anat. Rec.* 179(2):273-284, 1974.

Weanling Swiss mice, both male and female, were placed on various diets, and liver sections examined by electron microscope. In all livers, regardless of diet or mode of tissue fixation, the apposed plasma membranes of adjoining hepatocytes were often underlain by a single layer of extensive subsurface membranous cisterns. These structures were of 2 configurations: (1) Flat, uninterrupted, rather extensive cisterns, clearly originating from the rough endoplasmic reticulum with which they were occasionally in direct continuity. Such cisterns often bore ribosomes on their deep surfaces, never on the surfaces that faced the plasmalemma. (2) Linear arrays of small, elongated, flattened, highly fenestrated and smooth-surfaced saccules, appearing to originate from elements of the smooth endoplasmic reticulum with which there was occasional continuity. No cisterns were observed at the periphery of bile canaliculi or in conjunction with their microvillous linings; at the microvillous border of hepatocytes facing the space of Disse; or at tight or gap junctions. Small hiatuses which accommodated occasional desmosomes were also seen. In general, these cisterns do not represent elements of endoplasmic reticulum that have been passively displaced by encroaching glycogen deposits since they are found in livers of animals totally depleted of glycogen for long periods through special diets. Concerning the undetermined function of subsurface cisterns, one hypothesis states that they are related to the electrophysiological properties of plasma membranes while another theory postulates their relation to metabolic interchange at cell surfaces.

5767 HYPERSENSITIVITY GRANULOMA OF THE INTESTINE: AN EXPERIMENTAL STUDY. *(E.)* Rao, I. R.; Sharma, L. K.; Prakash, A. (All-India Inst. Med. Sci. New Delhi). *Indian J. Surg.* 35(8):386-392, 1973.

Hypersensitivity lesions were experimentally produced in adult guinea pigs and adult rabbits. Antigens used included crystalline egg albumin, normal horse serum, human serum, and old tuberculin. The animals were sensitized to the antigen by the multiple portal technique with 0.5-1 ml of antigen injected each time. On the 17th day, the first challenge dose, (0.1-0.3 ml) of antigen, was delivered, injected subserosally into the terminal ileum and into the cecum between the arterial arcades. A second challenge dose was given 3 days later at the same site. Of a total of 158 animals, including 58 sensitized with saline, 75 (47.5%) developed granulomata in their bowel as a response to foreign antigen. A significant number (68%) of these belonged to the test groups; 28 intestinal granulomas were associated with tuberculin, 22 with horse serum, 18 with egg albumin, and none with human serum. The 12 granulomata obtained in the control group probably resulted from the absorption of challenge dose leading to the production of low grade immunization and granulomata formation. Mesenteric lymphadenopathy, peritoneal fluid, and peritoneal adhesions were also more frequent in the test groups. These results suggest that hypersensitivity may be one of the factors in the pathogenesis of granulomatous lesions of the bowel, tubercular or otherwise. However, they do not suggest any direct similarity between the experimentally produced granulomata and clinically observed lesions.

5768 HISTOLOGICAL CHANGES IN THE MUCOSA OF THE SMALL INTESTINE AFTER EXPERIMENTAL TRUNCAL VAGOTOMY. *(Ger.)* Ihasz, M.; Szepeshazi, K.; Koiss, I. (Semmelweis Med. Univ., Budapest, Hungary). *Z. Exp. Chir. (Jena)* 6(5):346-352, 1973.

Histological examinations were performed on sections from the middle part of the small intestine (about 70 cm from the duodenojejunal flexure) of 24 dogs 5-365 days after truncal vagotomy. Moderate dilatation of the lymphatics was observed during the first 4 weeks after surgery. During weeks 6-17 the height of the villi increased by 1/4-1/2, and a parallel decrease occurred in the thickness of the villi. Villi returned to their original height after 5 months. No evidence of villar atrophy was ever seen. During the first 7 weeks inflammatory infiltrates of WBC, lymphocytes, and plasma cells formed. This infiltration was most pronounced at the base of the mucosa and in the tunica propria between the 7th week and the 4th month. The small intestine was histologically normal 7 months after vagotomy. These findings suggest that it is unlikely that morphological changes occurring in the small intestine after vagotomy could account for postvagotomy diarrhea. This diarrhea appears to be caused by interaction of a number of factors including circulatory disorders, an increase in the bacterial flora, changes in the concentrations of pancreatic enzymes and bile salts, passage of stagnant stomach contents into the intestine, and others.

5769 CHANGES IN THE FINE STRUCTURE OF MOUSE GASTRIC EPITHELIUM PRODUCED BY ETHANOL AND UREA. *(E.)* Eastwood, G. L.; Kirchner, J. P. (U. S. Naval Hosp., Philadelphia, Pa.). *Gastroenterology* 67(1):71-84, 1974.

The ultrastructural sequelae of 2 dissimilar gastric mucosal barrier breakers, ethanol and urea, were investigated. Fasted adult male Swiss mice received ethanol (10%, 10% + 100 mN HCl, 25%, 25% + 100 mN HCl), urea (300, 900, or 1500 mN), or control solutions for periods up to 15 min *via* esophageal intubation. Both ethanol and urea produced morphological changes in some animals as early as after 2 min exposure. The first observable effects of ethanol involved nuclear and cytoplasmic changes within the surface mucous cells without apparent disruption of the apical cell membranes or tight junctions. These findings indicate that the lipid solubility of ethanol may allow it to diffuse rapidly through the apical membranes or tight junctions without causing appreciable damage until it is within the cells. In contrast, urea solutions initially caused distortion of the tight junctions and formation of vacuoles within the surface mucous cells while the remainder of the cells appeared normal. It is possible that urea, being relatively unable to cross gastric epithelial membranes may cause injury *via* osmotic forces. These studies show that, although different gastric mucosal irritants produce similar physiological effects, they are not uniform in their morphological sequence of injury.

5770 ULTRASTRUCTURAL IMMUNOCYTOCHEMICAL LOCALIZATION OF LYSOZYME IN THE PANETH CELLS OF MAN. *(E.)* Erlandsen, S. L.; Parsons, J. A.; Taylor, T. D. (Univ. Iowa Coll. Med., Iowa City). *J. Histochem. Cytochem.* 22(6):401-413, 1974.

Human lysozyme was localized immunocytochemically at the ultrastructural level within Paneth cells of man by using an unlabeled antibody enzyme method. Thin sections of human jejunum and ileum were embedded in Araldite or Epon and staining was facilitated by etching with hydrogen peroxide. Sections of intestine on grids were stained by successive flotation on rabbit antihuman lysozyme antiserum, goat or sheep antirabbit IgG antiserum, and soluble peroxidase-rabbit antiperoxidase complex, followed by incubation with diaminobenzidine and hydrogen peroxide. No staining was observed after prolonged fixation of tissue in glutaraldehyde or treatment of tissue with uranyl acetate in block. The unlabeled antibody enzyme method was 100-1000 times more sensitive than immunofluorescence. Specific staining for lysozyme was observed over secretion granules in the apical cytoplasm, within the region of the Golgi apparatus, and within some, but not all, lysosomes. No staining was observed within the cisternae of the rough endoplasmic reticulum or other cellular organelles. In view of previous evidence for secretory activity in the basal cytoplasm where rough endoplasmic reticulum is predominant, it is suggested that lack of staining of such structures may be related to the absence of tertiary structure conferring antigenicity to the lysozyme molecule. The immunocytochemical studies suggest that the antigenicity of lysozyme is first acquired as the enzyme travels through the Golgi region and is indirectly supported by the morphologic finding that the electron-dense secretory product of the Paneth cell is also first recognizable within the Golgi complex.

5771 THE RE-EPITHELIZATION OF INTESTINAL MUCOSA IN GAMMA-IRRADIATED, PARTIALLY SHIELDED GNOTOBIOTIC PIGLETS. *(E.)* Mandel, L.; Moravek, F.; Miler, I. (Inst. Microbiol., Prague, Czechoslovakia). *Strahlentherapie* 147(3):308-314, 1974.

To test the hypothesis that partial shielding during irradiation could overcome bone marrow damage and that after this treatment "pure" gastrointestinal post-irradiation syndrome might develop, experiments were carried out in which 14-day-old germ-free, *Escherichia coli* O 54-monoassociated, and conventional piglets were shielded on the forebody up to the caudal end of the sternum during exposure to 1200, 1800, or 2400 r from a cobalt bomb. Parallel experiments were carried out with unshielded animals. The unshielded germ-free animals survived the different exposures for 11-14 days, wheras the *E. coli*-associated animals and conventional piglets survived for only 3-4 days. The shielded germ-free and *E. coli*-associated animals survived 1200 r for over 50 days, whereas conventional animals survived only 16 days; and the shielded germ-free and *E. coli*-associated animals exposed to 1800 or 2400 r survived 14-20 days compared to 3-8 days for the conventional animals under the same conditions. Histologically, the bone marrow of the shielded part was normal with a tendency to hyperfunction. In conventional animals of all groups except those exposed to 1200 r with shielding, the typical gastrointestinal post-irradiation syndrome was observed with denuded intestinal mucous membrane, deep necroses reaching the muscular tunic, and penetration of intestinal bacteria into the intestinal wall. In germ-free pigs, both hemorrhagic diathesis and partial denudation of the intestinal epithelium were considered to be the cause of death, but no explicit signs of irreparable damage were seen in the intestinal epithelium, and, at the time of death, reepithilization had begun in the mucosa. Findings for *E. coli*-associated animals were similar to those for the germ-free animals. The causes of death in the conventional animals appeared to be loss of water and electrolytes, nutritional impairment, and infection. These causes did not apply to the germ-free and *E. coli*-associated animals, which were not dehydrated: these animals seemed well nourished until death, and infection in the germ-free animals was ruled out. It is not known whether damage of the intestinal mucosa or hemorrhagic diathesis was the predominant cause of death in the germ-free and *E. coli*-associated animals.

5772 EXTRINSIC PARASYMPATHETIC INNERVATION OF THE DISTAL COLON. *(E.)* Meier-Ruge, W.; Hunziker, O. (Sandoz Ltd., Basel, Switzerland). *Abdom. Surg.* 16(5):139-148, 1974.

5773 "CAVEOLATED CELLS" CHARACTERIZED BY DEEP SURFACE INVAGINATIONS AND ABUNDANT FILAMENTS IN MOUSE GASTRO-INTESTINAL EPITHELIA. *(E.)* Nabeyama, A.; Leblond, C. P. (Dept. Anat., McGill Univ., Montreal, Canada). *Am. J. Anat.* 140(2):147-166, 1974.

5774 CHANGES IN THE MUCOSA OF THE SMALL INTESTINE FOLLOWING METHOTREXATE ADMINISTRATION OR ABDOMINAL X-IRRADIATION. *(E.)* Altmann, G. G. (Dept. Anat., Univ. Western Ontario, London, Canada). *Am. J. Anat.* 140(2):263-280, 1974.

5775 CELLS OF THE SPINAL TYPE IN THE GANGLIA OF THE LARGE INTESTINE. *(Rus.)* Lukashin, V. G. (I.P. Pavlov Inst. Physiol., Leningrad, USSR). *Arkh. Anat. Gistol. Embriol.* 64(4):39-43, 1973.

5776 REGENERATION OF THE MUSCULATURE OF THE LARGE INTESTINE UNDER EXPERIMENTAL CONDITIONS. *(Rus.)* Bazhenov, D. V. (Kalinin Med. Inst., USSR). *Arkh. Anat. Gistol. Embriol.* 64(6):81-85, 1973.

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

5777 RELATIVE AND ABSOLUTE GOBLET CELL NUMBERS IN INTESTINAL CRYPTS FOLLOWING IRRADIATION OR ACTINOMYCIN D. *(E.)* Cooper, J. W. (Allegheny Gen. Hosp., Pittsburgh, Pa.). *Experientia* 30(5):549-550, 1974.

5778 ABSENCE OF DILATED LATERAL INTERCELLULAR SPACES IN FLUID-TRANSPORTING FROG GALLBLADDER EPITHELIUM. DIRECT MICROSCOPY OBSERVATIONS. *(E.)* Frederiksen, O.; Rostgaard, J. (Inst. Exp. Med., Univ. Copenhagen, Denmark). *J. Cell Biol.* 61(3):830-834, 1974.

ABSORPTION—EXCRETION—TRANSPORT

5779 EFFECT OF ACUTE ETHANOL ADMINISTRATION ON DUODENAL CALCIUM TRANSPORT. *(E.)* Krawitt, E. L. (Dept. Med., Univ. Vermont, Burlington). *Proc. Soc. Exp. Biol. Med.* 146(2):406-408, 1974.

The effects of the acute administration of high concentrations of ethanol on calcium transport by the rat duodenum was investigated using *in vitro* everted gut sac technique. Albino male Sprague-Dawley rats were starved 24 hr before experimentation. One hr after administration of a large dose of ethanol (7.5 g/kg) intragastrically, there was a significant decrease in the ability of duodenal gut sacs to transport calcium, while no effect was apparent after i.p. administration (5.0 g/kg). The duodenum from rats which had received intragastric ethanol demonstrated necrosis of the villous epithelium and infiltration of the lymphocytes and plasma cells in the remaining crypts. No changes were seen after intragastric glucose administration or after i.p. administration of ethanol. When added directly to the incubation systems, concentratons of 0.1% and 1.0% ethanol did not diminish transport ratios, while a 1.5% solution significantly inhibited calcium transport by the duodenal gut sacs. Histological examination of gut sacs after incubation in mannitol and 2.6% ethanol revealed destruction of villous architecture with sloughed and shrunken epithelial cells containing granular vaculated cytoplasm and pyknotic nuclei from the sacs. Similar but less striking changes were seen after incubation in 1.5% ethanol. The results suggest that the inhibition of calcium transport seen after acute administration of ethanol is the result of a direct toxic effect on the intestinal epithelium.

5780 MECHANISM AND SITE OF VITAMIN K-3 SMALL INTESTINAL TRANSPORT. *(E.)* Hollander, D.; Truscott, T. C. (Albany Med. Coll., N.Y.). *Am. J. Physiol.* 226(6):1516-1522, 1974.

To identify the mechanism of *in vitro* transport of vitamin K-3 and to localize the site of such absorption as to possible regional differences, the entire small intestine distal to the common bile duct of male Sprague-Dawley rats was excised and everted. Proximally and distally, 8.5 cm segments were incubated with 75-900 μM concentrations of micellar ^{14}C-labelled vitamin K-3 in solution. The transport rate was a linear function of the vitamin concentration up to 900 μM; at 300 μM, the absorption rate was 5.46 nM/min/100 mg of proximal intestine and 12.56 for the distal segment under O_2. These rates were not altered under N_2 or with the metabolic uncoupler 2,4-dinitrophenol, or in the absence of bile salts and fatty acids. Transport of the vitamin in a serosal-to-mucosal direction was also seen. No absorption occurred in the absence of a transmural concentration gradient. Results of all experiments showed a significantly greater transport of vitamin K-3 by the distal small bowel than by the proximal. This predilection for distal transport was shared by a C_8 fatty acid, octanoate, but a water-soluble compound, erythritol, was absorbed to a greater degree proximally, these 2 substances being used to check the possibility that greater distal transport of vitamin K-3 might be unique to the vitamin. In general, the findings indicate that small intestine transport of vitamin K-3 is due to a bidirectional passive diffusion process occurring more rapidly in the distal part.

5781 ABSORPTION AND PASSAGE OF FAT- AND WATER-SOLUBLE THIAMIN DERIVATIVES INTO ERYTHROCYTES AND CEREBROSPINAL FLUID OF MAN. *(E.)* Baker, H.; Thomson, A. D.; Frank, O.; Leevy, C. M. (New Jersey Med. Sch., East Orange). *Am. J. Clin. Nutr.* 27(7):676-680, 1974.

Results of a study to compare human absorption of 4 thiamin derivatives and their abilities to penetrate red blood cells *in vivo* as well as to pass into the cerebrospinal fluid are presented. The compounds, lipid-soluble thiamin propyl disulfide and thiamin tetrahydrofurfuryl disulfide, and water-soluble thiamin hydrochloride and thiamin pyrophosphate, all showed full thiamin activity with the Ochromonas danica growth test. At weekly intervals, 24 healthy subjects (aged 30-50) were given 50 mg. p.o. or i.v. of a different form of thiamin, and the same procedures for analysis were followed each time. Oral administration of thiamin propyl disulfide and thiamin tetrahydrofurfuryl disulfide caused a significant increase in thiamin activity in whole blood, RBC and cerebrospinal fluid, equivalent to that produced by i.v. administration of the water-soluble thiamin hydrochloride and thiamin pyrophosphate. In contrast, oral administration of the water-soluble thiamins did not significantly elevate thiamin, probably due to their rate-limited intestinal transport. The garlic-like odor of thiamin propyl disulfide limits its usefulness in multivitamins and food fortification, but thiamin tetrahydrofurfuryl disulfide is odorless and therefore more useful. In addition, the lack of toxicity and high oral effectiveness of the fat-soluble thiamins should make them preferable to the water-soluble forms for treating thiamin deficits associated with malnutrition, liver disease, beriberi, and alcoholic cerebellar-cortical degeneration.

5782 SITE OF BILIARY PHOSPHOLIPID ABSORPTION IN THE SMALL INTESTINE OF THE RAT. *(E.)* Ulrich, C.; Boucrot, P.; Clement, J. (Animal Physiol. Nutr. Lab., Dijon, France). *Biochimie* 56(3):429-434, 1974.

Isolated phospholipids labeled with ^{14}C-1-oleic acid and biliary lipids labeled with ^{3}H,9-10-oleic acid were both perfused into the duodenum of 2 male Wistar rats. In one experiment fresh bile was introduced; while in two additional experiments bile lipids according to the Delsal or Folch methods were used. The radioactivity recovered in the lumen and the mucosa lipids of 3 intestinal segments (upper, middle, and lower) was measured. In any case, the ^{14}C and ^{3}H radioactivity was mainly recovered along the upper and middle segments. When the perfused phospholipids were isolated, ^{14}C and ^{3}H fatty acids and ^{14}C and ^{3}H triglycerides appeared in the lumen and mucosa, resp., but, when the mixture contained tritiated bile, the ^{3}H radioactivity was recovered mainly as phospholipids in the upper and middle segments of the small intestine. These studies demonstrated that the bile ^{3}H phospholipids and the isolated ^{14}C phospholipids were both absorbed by the upper and middle segments of the small intestine and that biliary phospholipids and biliary salts were not simultaneously absorbed in the ileum. This obviously suggests the disorganization of the biliary complex in the small intestinal lumen.

5783 THEORETICAL MODEL STUDIES OF INTESTINAL DRUG ABSORPTION IV: BILE ACID TRANSPORT AT PREMICELLAR CONCENTRATIONS ACROSS DIFFUSION LAYER-MEMBRANE BARRIER. *(E.)* Ho, N. F. H.; Higuchi, W. I. (Coll. Pharm., Univ. Michigan, Ann Arbor). *J. Pharm. Sci.* 63(5):686-690, 1974.

Based on the first principles of transport, thermodynamics, and various biological and physico-chemical relations known about the transport of bile acids in dilute solutions, a general physical model using mathematics is described for the simultaneous active and passive transport of conjugated and unconjugated bile acids from nonmicellar solutions in the ileum. It reduces to the passive absorption mechanism in the duodenum and jejunum. The model provides the basis for experimental design of *in situ* studies and the quantification of physically meaningful and experimentally accessible transport parameters and of the effect of functional groups on bile acids. The interaction and factorization of (a) the permeability of the stagnant water layer, the lipoidal and aqueous channel pathway of the membrane according to the diffusion mechanisms; (b) the permeability of the membrane according to the active mechanism; (c) the bile acid concentration dependence; and (d) the pH and pKa are mathematically explicit. Theoretical computations indicate that the stagnant water layer may be the rate-determining barrier. A model is also described for the first-pass absorption of bile acids from dilute solutions in the small intestine.

5784 STUDIES ON THE TRANSPORT OF GLUCOSE FROM DISACCHARIDES BY HAMSTER SMALL INTESTINE IN VITRO. II. CHARACTERISTICS OF THE DISACCHARIDASE-RELATED TRANSPORT SYSTEM. *(E.)* Ramaswamy, K.; Malathi, P.; Caspary, W. F.; Crane, R. K. (Rutgers Med. Sch., Piscataway, N.J.) *Biochim. Biophys. Acta* 345(1):39-48, 1974.

Disaccharidase-associated transport of glucose from sucrase was investigated in the hamster small intestine. Two kinds of intestinal preparations were used for studies of uptake, namely, rings of everted intestine and everted sacs tied to polyethylene tubing. Results obtained with the latter preparation were deemed clearer since access of substrate to the serosal surface and possible hydrolysis by an internal disaccharidase was thereby prevented. Incubations were generally carried out with high ratios of medium to tissue (50 ml to 0.3 g), at high shaking rates (200 cycles/min), and for short time periods (2 min) to minimize build-up of high concentrations of glucose at the tissue surface and in the medium. For the Na^{+}-free Krebs-Ringer buffer used, choline chloride was substituted for NaCl and potassium phosphate for sodium phosphate. The transport of glucose from sucrose was found to be substantially independent of Na^{+}, thus differing from the Na^{+}-dependent transport of monosaccharide. In the absence of Na^{+}, glucose released from sucrose did not mix with a pool of added free glucose but was directly transferred. Maltose, isomaltose, and trehalose acted similiarly to sucrose. Both monosaccharides released from sucrose were transferred. The extent of uptake was not related to total sucrase activity. The explanation was offered that brush border disccharidases subserve a translocating "carrier" function and that the enzymes are organized in the membrane in such a way that they can accept substrate on one side of the membrane and deliver a part of the product on the other.

5785 ABSORPTION OF AMINO ACIDS IN MALNOURISHED RATS. *(E.)* Wapnir, R. A.; Lifshitz, F. (North Shore Univ. Hosp., Manhasset, N.Y.). *J. Nutr.* 104(7):843-849, 1974.

The absorption of amino acids in young Wistar rats fed protein and protein-energy deficient diets was studied *in vivo* using a perfusion technique of intestinal segments. The diets had the following composition: A) 18% protein, 69% carbohydrate, and 8% fat (CTL); B) 4% protein, 14% cellulose, and no changes in other constituents (LPR); C) 4% protein, 56.5% carbohydrate, and 26.5% cellulose (LPC). The LPR and LPC rats failed to gain weight and became hypoproteinemic after feeding the diets for 4 weeks. At the end of this period, the intestinal transport of tyrosine was higher in the LPR and LPC rats as compared with the CTL animals. The lumen-to-blood flow of ^{3}H-tyrosine was also increased in LPR and LPC rats. However, the uptake of this amino acid by the soluble and protein-bound extracts of the intestinal mucosa was not altered, and there was no relation between the absorption of tyrosine and the free amino acid levels of the intestinal mucosa. The intestinal absorption of tyrosine was inversely correlated with the circulating blood levels. The intestinal transport of leucine was also elevated in malnourished animals, but whole blood levels of this amino acid were unchanged. The intestinal transport rates of phenylalanine and glycine were not altered, although glycinemia was elevated in both LPR and LPC rats. The absorption of lysine was lower in the LPR group while blood levels were not modified. The results of this study suggest that in malnourished rats, the intestinal transport of certain neutral amino acids such as tyrosine may be inversely correlated with its concentration in the circulation. However, there was no such correlation for glycine, leucine and lysine.

5786 TRANSPORT OF L-METHIONINE IN RAT INTESTINE AND KIDNEY. *(E.)* Bartsocas, C. S.; Thier, S. O.; Crawford, J. D. (Massachusetts Gen. Hosp., Boston). *Pediatr. Res.* 3(6):673-678, 1974.

L-Methionine transport was studied *in vitro* in kidney cortex slices and intestinal segments from male Sprague-Dawley rats. In both tissues L-^{14}C-methionine (0.065 mM) was accumulated against a chemical concentration gradient by processes which obeyed saturation kinetics. In both tissues anerobic conditions inhibited methionine accumulation. The processes were sodium dependent. Addition of sucrose (0.3 M) produced significant inhibition of L-methionine accumulation in the kidney. L-Methionine transport was essentially independent of pH. With the exception of valine and ethionine, amino acids representative of the neutral, dibasic, and imino groups did not inhibit methionine transport at 2.4 mM concentrations. Valine was a potent inhibitor of transport in the intestine and ethionine of uptake in the kidney. Methionine inhibited glycine accumulation in kidney and intestine but did not affect lysine transport in either tissue. These data indicate that methionine uptake in the gut and kidney has the characteristics of an active transport process that is unaffected by most other amino acids. It is also suggested that methionine is transported by an independent mechanism or by a transport system shared with other neutral amino acids but for which it has a much higher affinity.

5787 DIGESTA PASSAGE AND WATER EXCHANGE IN THE EQUINE LARGE INTESTINE. *(E.)* Argenzio, R. A.; Lowe, J. E.; Pickard, D. W.; Stevens, C. E. (New York State Vet. Coll., Cornell Univ., Ithaca). *Am. J. Physiol.* 226(5):1035-1042, 1974.

Digesta flow and water absorption were studied in 48 Shetland ponies fed a conventional diet or a high-cellulose, low-protein diet with added soluble carbohydrates, minerals, and vitamins which was designed to maximize microbial digestion. Animals were fed 2 meals/day at 12 hr intervals. Liquid markers (polyethylene glycol and ^{51}Cr-ethylenediaminetetraacetic acid) and particulate markers (radiopaque polyethylene tubing) were administered during the morning meal *via* stomach tube, cecal fistula, or dorsal colonic fistula. Following sacrifice of the animals at various times up to 48 hr after marker administration, 12 digestive tract segments were separately analyzed for water, marker content, and osmolality. In control animals the greatest percentage of liquid marker had reached the cecum 2 hr after its administration, while 75% of particulate markers still remained in the stomach. In animals on the experimental diet, small intestinal transit of marker was significantly slower, but differences between the 2 groups in large intestinal transit were not significant by 8 hr after feeding. Both fluid and particulate markers rapidly left the cecum and passed into the large ventral dorsal colon where major retention occurred. Markers accumulated rapidly in both the right and left ventral colon. They were released at a slower rate into the dorsal colon, suggesting that the ventral-dorsal colonic junction is a major barrier to digesta flow. Slow release of markers from the dorsal colon indicated that its termination is another major barrier to outflow. In animals fed the conventional diet, large, cyclic exchanges of water occurred between digesta and plasma and were associated with changes in osmotic gradients. The daily volume of water entering the large intestine from the small bowel, plus that entering *via* the large intestinal mucosa was equal to total extracellular fluid volume. Of this, 95% was reabsorbed. Net daily absorption of water in the cecum of animals on the experimental diet was 1/3 that of controls. This decrease was accompanied by a 65% increase in net absorption of water from the ventral and small colons and a 50% decrease in net water secretion into the dorsal colon. Diarrhea was apparently prevented by compensatory changes which took place in the colon. It is noted that the cecum of the pony differs from that of the rabbit which retains fluid marker for long periods and can selectively reject particulate markers. Further, there is apparently no retrograde movement of markers from the proximal colon into the cecum of the pony.

5788 IN VIVO INTESTINAL ABSORPTION OF HEXOSE IN GROWTH-RETARDED SUCKLING RAT PUPS. *(E.)* Younoszai, M. K.; Lynch, A. (Dept. Pediatr., Univ. Iowa, Iowa City). *J. Nutr.* 104(6):671-677, 1974.

The possible effects of malnutrition during infancy on growth retardation were investigated in Holtzman rats. Growth retardation was induced by increasing the litter size from 16 to 18 pups on the second day after delivery. Absorption of 3-*O*-methyl-D-glucose was measured in the jejunum plus ileum of growth retarded and control pups using an *in vivo* perfusion technique under steady state conditions. At 7 to 8 days of age the size of the jejunum + ileum and mean rate of absorption of 3-*O*-methyl-D-glucose normalized for intestinal size were similar in growth retarded and control pups, 65 and 54 mg/g jejunum + ileum dry weight/hr, resp. At 14 to 15 days, although intestinal size was smaller in growth retarded than in control animals, the rate of absorption of 3-*O*-methyl-D-glucose was about 2-fold and significantly higher in growth retarded than control pups, 126 and 74 mg/g jejunum + ileum dry weight/hr, resp. At 21 and 22 days, submaximal absorption rates from a 10 mg/ml solution were similar in growth retarded and control animals 225 and 222, resp., but from a 15 mg/ml solution the value was significantly lower in growth retarded than in control pups, 240 vs 295, resp. The results suggest several conclusions. The decreased total amount and somewhat lower rate of hexose absorption in the growth retarded pups may be contributing factors toward perpetuation of growth retardation. As in the intestine of the adult malnourished rat, the specific activity of hexose absorption seems also to be enhanced transiently in the intestine of growth-retarded rat pups. The somewhat higher intestinal tissue concentrations of 3-*O*-methyl-D-glucose in the growth retarded pups were probably due to higher mean luminal 3-*O*-methyl-D-glucose concentration in these pups. Plasma concentrations of 3-*O*-methyl-D-glucose were similar in the 2 groups. Thus, in these *in vivo* studies, tissue and plasma 3-*O*-methyl-D-glucose concentrations did not correlate well with the 3-*O*-methyl-D-glucose absorption rates. Growth retardation did not appear to have any effect on intestinal water absorption.

5789 THE MECHANISM OF INTESTINAL ABSORPTION OF PHOSPHATIDYLCHOLINE IN RATS. *(E.)* Parthasarathy, S.; Subbaiah, P. V.; Ganguly, J. (Indian Inst. Sci., Bangalore, India). *Biochem. J.* 140(3): 503-508, 1974.

Phosphatidylcholine (20 µM) specifically labeled in the fatty acid or in the glycerol moiety or with ^{32}P was injected into the intestine of rats. Compared with the 1-([^{14}C]acyl) derivative, 2-([^{14}C] acyl) phosphatidylcholine gave more radioactive unesterified fatty acids and correspondingly less radioactive lysophosphatidylcholine in the lumen as well as in the mucosa. Both compounds led to the appearance of significant amounts of radioactive triacylglycerols in the mucosa. Injection of ^{32}P-phosphatidylcholine or ^{32}P-lysophosphatidylcholine resulted in the appearance of radioactive glycerylphosphorylcholine, glycerophosphate, and Pi in the mucosa. Compared with the radioactivity of phosphatidylcholine, that of lysophosphatidylcholine virtually disappeared from the lumen. Glycerylphosphorylcholine diesterase was highly active in the mucosa and was concentrated in the microsomal fractions or in the brush-border free particulate materials of the mucosal cell. It is concluded that dietary phosphatidylcholine is hydrolyzed in the intestinal lumen by the pancreatic phospholipase A to 1-acylglycerylphosphorylcholine, which on entering the mucosal cell is partly reacylated to phosphatidylcholine while the rest is further hydrolyzed to glycerylphosphorylcholine, glycerophosphate, glycerol, and Pi. The fatty acids and glycerophosphate are then reassembled to give triacylglycerols *via* the Kennedy (1961) pathway.

5790 EFFECTS OF WATER INTAKE ON INTESTINAL ABSORPTION AND MOTILITY IN THE WATER-DEPRIVED DOG. *(Fr.)* Ardisson, J. L.; Smutek, V.; Catier, J.; Dolisi, C.; Gastaud, M. (U.E.R. Med., Marseille, France). *J. Physiol. (Paris)* 68(1):27-35, 1974.

MOTILITY

5797 INTESTINAL EFFECTS OF 5-HYDROXYTRYPTAMINE AND MORPHINE IN GUINEA PIGS, DOGS, CATS AND MONKEYS. *(E.)* Pruitt, D. B.; Grubb, M. N.; Jaquette, D. L.; Burks, T. F. (Univ. Texas Med. Sch., Houston). *Eur. J. Pharmacol.* 26(2):298-305, 1974.

Although evidence has been advanced that the intestinal stimulatory effects of morphine are mediated in the dog largely by release of endogenous 5-hydroxytryptamine (5-HT), in the guinea pig morphine antagonizes the intestinal stimulatory properties of 5-HT. To determine whether the inhibitory effect of morphine on intestinal responses to 5-HT is unique to the guinea pig, studies were carried out in guinea pigs, dogs, cats, and monkeys. Intestinal intraluminal pressures were measured after i.v. administration of 100 μg/kg 5-HT and also after administration of 100 μg/kg morphine followed by 100 μg/kg 5-HT. In guinea pigs, but not in the other species, the intestinal stimulatory effect of 5-HT was antagonized by morphine. Since the nervous structures in the guinea pig are easily blocked by 5-HT itself and by a wide variety of narcotic drugs, it is concluded that the neuronal 5-HT receptors or the postganglionic neural elements in the guinea pig intestine are somehow different from analogous elements in other species.

5798 INTERACTIVE GRAPHICS ANALYSIS OF GASTROINTESTINAL ELECTRICAL SIGNALS. *(E.)* Linkens, D. A.; Cannell, A. E. (Dept. Control Engineer., Univ. Birmingham, England). *IEEE Trans. Biomed. Eng.* BME-21(4):335-339, 1974.

A set of conversational correlation and spectral computer programs for analysis of slow waves from human and canine digestive tracts is described. The data analyzed comprise electrical signals obtained from either the inside or outside walls of the stomach and small and large bowels. The basic rhythm is a low-frequency wave of about 0.05 Hz in the stomach and 0.2 Hz in the duodenum of man, and about 0.1 Hz in the stomach and 0.3 Hz in the duodenum of dogs. Interactive analysis makes it possible to accurately investigate changes in phase shifts and frequency spectra caused by drug stimulation, pyloroplasty, and different types of vagotomy.

5799 THE EFFECT OF GASTRIC DISTENTION ON GASTRIC MOTILITY AND SERUM GASTRIN IN ACUTELY VAGOTOMIZED PIGS. *(E.)* Stadaas, J.; Schrumpf, E.; Haffner, J. F. W. (Ulleval Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(2):127-131, 1974.

Gastric motility and gastrin release after stepwise gastric distention were measured before and after vagotomy in pigs. Motility recordings were obtained separately from the antral and fundal portions of the stomach by sectioning the organ. The effects of gastric distention were significantly altered after vagal denervation. Increases in serum gastrin and antral peristalsis seen after stepwise distention were diminished after vagotomy. Basal pressure increments were more marked in the antral as well as the fundal portions of the stomach, and the fundal and antral adaptation times were prolonged after vagal denervation. The data indicate that vagotomy alters motility in both the distal and proximal parts of the stomach, suggesting that even proximal vagotomy produces changes in gastric motor function. In addition, intact antral innervation appears to be necessary for normal gastrin release after distention.

5800 CORRELATIONS BETWEEN ELECTROLYTE CONTENT AND SPONTANEOUS ELECTRICAL ACTIVITY IN INTESTINAL MUSCLE. *(E.)* Job, D. D.; Bloomquist, W. E.; Bridgeforth, J. (Eli Lilly Co. Res. Lab., Indianapolis, Ind.). *Am. J. Physiol.* 226(6):1502-1509, 1974.

Spontaneous *in vitro* electrical activity was recorded from five different regions of cat small intestine. The electrolyte content was determined in these same pieces of tissue. Gradients in slow-wave frequency (SWF) and "apparent" slow-wave conduction time (SWC) were observed down the intestine. Correlations between ion levels and electrical parameters and correlations between electrical parameters themselves were computed. Slow-wave amplitude (SWA) was negatively correlated with both tissue sodium and calcium. Spike amplitude was negatively correlated with tissue calcium and sodium and positively correlated to potassium. The latter was the strongest of the three. Spike frequency was negatively correlated with chloride. Slow wave and spike conduction were not highly correlated to any ions. SWF was not correlated with any ion which exhibited a significant gradient, indicating that the gradient in intestinal motor activity was not primarily ionic in origin. A positive correlation between SWA and SWF was the most prominent interaction among electrical parameters. Most interactions between electrical parameters were insignificant. Most correlations between ion levels and electrical parameters were below .50, suggesting that the bulk-phase ion distribution is not the primary determinant of the spontaneous electrical activity.

5801 ELECTROMYOGRAPHIC STUDY OF THE SPHINCTER OF ODDI. I. TECHNIQUE AND IN VIVO AND IN VITRO RESULTS FROM RABBITS. *(Fr.)* Sarles, J. C.; Midejean, A.; Gayne, F. (Res. Unit. Dig. Dis., Marseille, France). *Biol. Gastroenterol. (Paris)* 7(1):19-27, 1974.

A technique was developed by which simultaneous recordings could be made of electrical activity in the sphincter of Oddi and of pressure fluctuations within the common bile duct. *In vitro* experiments were performed on 20 rabbits. Measurements made in the sphincter of Oddi, isolated from the duodenum, showed salvos of 3-7 spike potentials varying from about 12-200 microvolts in amplitude and lasting for 1-2 sec. The intervals between these salvos lasted 3-15 sec (average of 5 sec). Each salvo corresponded to an increase of pressure within the common bile duct. These pressure increases ranged from 1-23 cm H_2O and were proportional to the frequency and amplitude of spike potentials in the biliary tract. Similar results were obtained with the sphincter of Oddi when it was not isolated from the duodenum. No correlation was found between electrical activity in the duodenum and pressure increases in the biliary tract. *In vivo* studies performed on 50 fasted rabbits anesthetized with pentobarbital sodium revealed salvos of 1-8 spike potentials separated by intervals of 1-10 sec (average of 3-5 sec) in the sphincter of Oddi. Biliary pressure increased immediately after these salvos. Duodenal spike potentials had a different rhythm from those recorded in the sphincter of Oddi and they were not accompanied by increases in biliary tract pressure. Electrical activity in the sphincter of Oddi was also shown to be independent of ECG tracings and respiratory movements when the rabbits were properly anesthetized. These findings differ from others reported in the literature in which electrical activity in the duodenum and sphincter of Oddi coincided. This difference may be due to anatomical differences in the experimental animals employed. Rabbits were chosen for this investigation because their sphincter of Oddi is independent of the duodenal musculature.

5802 EFFECT OF GASTRIC FUNDECTOMY ON CANINE GASTRIC ELECTRICAL AND MOTOR ACTIVITY. *(E.)* Wilbur, B. G.; Kelly, K. A.; Code, C. F. (Mayo Med. Sch., Rochester, Minn.). *Am. J. Physiol.* 226(6):1445-1449, 1974.

In five dogs with implanted gastric electrodes, the mean frequency of the gastric pacesetter potential (PP) decreased before fundectomy from 5.0 to 4.2 cycles/min within 1 min after instillation of 400 ml of 154 mM NaCl and then gradually returned toward control. By 10 min, a mean of 131 ml of saline had emptied from the stomach. Mean gastric transmural pressure increased from 1.5 to 9.8 cm H_2O with gastric distention from 0 to 400 ml but did not increase further with continued distention to 800 ml. In identical tests after fundectomy, a greater decrease in frequency of the PP occurred with instillation of saline (mean decrease, 2.4 cycles/min), gastric emptying of instilled saline was faster (mean volume emptied in 10 min, 251 ml), and greater increases in pressure resulted from gastric distention (mean pressure at 400 ml, 17.6 cm H_2O). Vomiting occurred with 600 or 700 ml. Results show that the fundus acts as a reservoir and participates in the control of gastric emptying of instilled saline by regulating intragastric pressure.

5803 INFLUENCE OF FAT AND FLUORIDE ON GASTRIC EMPTYING OF RATS. *(E.)* McGown, E. L.; Suttie, J. W. (Dept. Biochem., Univ. Wisconsin, Madison). *J. Nutr.* 104(7):909-915, 1974.

An increase of dietary fat from 5 to 25.5% (35% of nutrients) markedly enhanced the growth-depressing action of dietary fluoride (600 ppm) in female Sprague-Dawley rats. Two separate p.o. doses of 1 mg fluoride caused a 14-hr lag in $^{14}CO_2$ production from ^{14}C-tripalmitin in a corn oil test meal. Fluoride also delayed $^{14}CO_2$ production from ^{14}C-palmitate; this experiment indicated that depressed intraluminal lipolysis did not account for the effect of fluoride on ^{14}C-tripalmitin metabolism. By monitoring the passage of several ^{14}C-substrates through the gastrointestinal tract, fluoride in the presence of fat was found to delay gastric emptying. After a labeled test meal of 0.65 g corn oil, the percentage of radioactivity remaining in the stomach of the fluoride-treated (1 mg) animals was 80 and 73% at 3 and 5 hr, resp., compared with 24 and 6% in controls. When rats were given test meals of a semipurified diet containing 35% corn oil, fluoride again caused a striking delay in disappearance of radioactivity: 79 and 64% of radioactivity remained at 3 and 5 hr, resp., compared with 40 and 39% in controls. With fat-free meals, there was a slight effect of fluoride at 1 hr (42% radioactivity remaining), but no difference from controls at 3 hr. The effect of fluoride on gastric emptying could account for the increased toxicity of fluoride to rats fed high-fat diets.

5804 A POSSIBLE ORIGIN OF INTESTINAL GRADIENTS AND THEIR RELATION TO MOTILITY. *(E.)* Job, D. D.; Griffing, W. J.; Rodda, B. E. (Lilly Res. Lab., Eli Lilly Co., Indianapolis, Ind.) *Am. J. Physiol.* 226(6):1510-1515, 1974.

In an effort to determine whether degree of interaction between mitochondria and plasma membrane could be related to slow-wave frequency in the intestine, sections of longitudinal muscle from the proximal jejunum and distal ileum of the cat were examined quantitatively by the electron microscope. Mitochondria were found to be clustered near the plasma membrane or near the nucleus. Of those near the membrane, the ones in the ileum were, on the average, 5 times farther from the membrane than were the ones in the jejunum. These differences alone were believed to be sufficient to account for the slower frequency of electrical slow waves observed in the ileum. The greater diameter observed for cells in ileal sections also could account for slower slow-wave conduction. It was proposed that closeness of mitochondria to plasma membrane may determine the rate at which ATP and ADP are recycled between the 2, and that this affects the frequency of intestinal slow waves. Finally, more mitochondria per micrometer of perimeter were found in jejunum than in ileum, and this suggested that the total energy output is greater in the former, therby accounting for metabolic gradients seen in the small intestine, relating to level of oxygen consumption, level of ATP, and level of various enzymes and transmitters.

5805 STUDIES OF GASTROINTESTINAL INTERACTIONS. VI. INTESTINAL FLOW, MEAN TRANSIT TIME, AND MIXING AFTER COMPOSITE MEALS IN MAN. *(E.)* Lagerlof, H. O.; Johansson, C.; Ekelund, K. (Karolinska Hosp., Stockholm, Sweden). *Scand. J. Gastroenterol.* 9(3):261-270, 1974.

The postprandial flow in the jejunum was investigated with a multiple indicator dilution technique by which the changes in transit times of the intestinal contents were considered. Two composite meals, which differed in their glucose content, were fed to 7 healthy subjects on different occasions. One meal contained 3.6 g protein, 5.1 g lactose, 5.9 g corn oil, and 3.0 polyethylene glycol/100 ml. The other meal contained in addition 10 g glucose/100 ml. Despite a pronounced lower gastric emptying rate of the meal containing glucose, the flow volumes in jejunum were similar after the meals, owing to a dilution of the hypertonic meal during intestinal transit. A flow volume of about 500 ml had passed at the investigated jejunal level after 3 hr. Flow rates of about 2 ml/min persisted after 2 hr. The transit times of the intestinal contents did not differ significantly between the meals, irrespective of the differences in gastric emptying rates. The mean transit time increased during the first hr after ingestion, and undulated thereafter between 20 to 40 min in the individual experiments. Based on the assumption of a constant velocity of the indicator particles, the transit of the indicator through the entire intestine could be estimated, as could the distribution of test meal marker in consecutive segments of the intestine.

5806 HYPOTONIC ROENTGENOGRAPHY WITH GLUCAGON. *(E.)* Miller, R. E.; Chernish, S. M.; Skucas, J.; Rosenak, B. D.; Rodda, B. E. (Indiana Univ. Sch. Med., Indianapolis). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 121(2):264-274, 1974.

In a hypotonic gastrointestinal study, 24 asymptomatic men (aged 20-54 yr) were divided into 2 groups of 12 each. In one group glucagon (2 mg) was compared with placebo and atropine sulfate (1 mg). In the 2nd group, glucagon was compared with placebo and propantheline bromide (30 mg). Drugs were given i.m., double-blind, and crossover. Glucagon decreased the motility and tonicity of the stomach and duodenum to a significantly greater degree than placebo at 10 and 30 min. At 60 min the effects of glucagon differed little from those of placebo. Stomach and small intestine tonicity and motility were significantly decreased at 10, 30, and 60 min following atropine sulfate and propantheline bromide. Tonicity and motility of the duodenal bulb at 60 min and the duodenal loop at 30 and 60 min were also decreased following administration of the anticholinergics. Glucagon was significantly better than either anticholinergic for roentgenographic examination of the stomach, duodenal bulb, and duodenal loop. Side effects of propantheline bromide included dryness of the mouth (all 12 subjects), nausea (5), headaches (6), and urinary retention (10). The most frequent side effects of atropine were dryness of the mouth (8 cases) and nausea (3). Glucagon caused nausea (average of 7.5 reports) and vomiting (average of 4.5 reports), but these side effects lasted only 5-10 min.

5807 STUDIES ON THE NECESSITY OF A BOLUS FOR THE PROGRESSION OF SECONDARY PERISTALSIS IN THE CANINE ESOPHAGUS. *(E.)* Janssens, J.; Valembois, P.; Hellemans, J.; Vantrappen, G.; Pelemans, W. (Gastrointest. Dis. Lab., Leuven, Belgium). *Gastroenterology* 67(2):245-251, 1974.

An investigation was made to determine whether the progression of secondary esophageal contractions depends upon the presence of an intraluminal bolus. Without interfering with the vagal innervation, transection of the esophagus with bolus deviation was performed in dogs both at the cervical and at the thoracic level. If the instilled bolus (5-10 ml of water) was deviated at the cervical level, a secondary wave elicited in the upper part of the gullet was not able to progress in a peristaltic manner. However, in the thoracic esophagus, the bolus was not required for normal peristaltic progression of the secondary contraction. Secondary peristaltic contractions elicited below a cervical or a thoracic transection frequently started in the esophageal segment above the transection level in the absence of any bolus. These results suggest that in the canine esophagus, the progression of secondary peristaltic contractions is regulated in the same manner as primary peristalsis, i.e. by the cooperation of at least two mechanisms: the central regulating mechanism in the brain stem, and afferent information originating in the esophageal wall from the presence of an intraluminal bolus. The bolus is a prerequisite at the cervical level, but not at the thoracic level, although even in the thoracic gullet the peristaltic progression of the secondary contraction is improved by the presence of a bolus.

5808 PRESYNAPTIC INHIBITION AT MAMMALIAN PERIPHERAL SYNAPSE? *(E.)* Hirst, G. D. S.; McKirdy, H. C. (Dept. Physiol., Monash Univ., Clayton, Australia). *Nature (Lond.)* 250(5465):430-431, 1974.

Intracellular recordings were made from myenteric neurons in flaps of plexus attached to the distal end of an adjacent segment of guinea pig mid small intestine. The periarterial nerves leading to the intestinal segment were drawn into a suction electrode and stimulated electrically. Synaptic activity was evoked in the myenteric plexus by use of a pair of fine platinum electrodes with one under and the other just above the plexus flap. Synaptic activity was also evoked by distending a balloon placed inside the lumen of the gut segment. In most experiments, trains of 10-100 stimuli applied to periarterial nerves produced no change in the electrical properties of the myenteric neurons. Transmural stimulation of the flap of myenteric plexus never evoked inhibitory postsynaptic potentials. An intermittent discharge of excitatory postsynaptic potentials was recorded from some neurons in the absence of any apparent stimulus. Close transmural stimulation evoked a single excitatory postsynaptic potential or a cluster of excitatory postsynaptic potentials. A preceding train of stimuli applied to periarterial nerves either abolished the synaptic response or reduced the number of excitatory postsynaptic potentials in the cluster. When intracellular recordings were made from longitudinal or circular muscle, trains of stimuli (20 Hz for 5 sec) applied to periarterial nerves produced no detectable change in membrane potential of cells in longitudinal muscle, but they did cause detectable hyperpolarization of circular muscle membrane potential. These findings suggest that sympathetic inhibition is mediated presynaptically rather than by the postsynaptic action of inhibitory transmitter.

5809 DEVELOPMENTAL CHARACTERISTICS OF LOWER ESOPHAGEAL SPHINCTER FUNCTION: A POSSIBLE MECHANISM FOR INFANTILE CHALASIA. *(E.)* Cohen, S. (Hosp. Univ. Pennsylvania, Philadelphia). *Gastroenterology* 67(4):252-258, 1974.

The developmental characteristics of lower esophageal function were investigated in anesthetized opossums. At ages 35 days and 84 days opossums had mean lower esophageal sphincter pressures of 4.3 mm Hg and 12.6 mm Hg, resp., compared with 28 mm Hg in adult animals. Dose-response curves to gastrin I (0.1-4.0 μg/kg i.v.) were displaced to the right, and the maximum response was reduced in younger animals. The maximum percentage of lower esophageal sphincter response to norepinephrine (20 μg/kg i.v.) was similar in all animals. *In vitro* studies demonstrated that maximum responses of lower esophageal sphincter muscle to acetylcholine, norepinephrine, and potassium chloride depolarization were similar when the responses were corrected for differences in muscle weight. The response to gastrin I was reduced in muscle from younger animals. The results of these studies suggest that the reduced lower esophageal sphincter pressure in the young opossum is associated both with a smaller muscle mass and a reduced response to gastrin I. These developmental changes in lower esophageal sphincter may provide a physiological explanation for chalasia of infancy.

5810 EFFECT OF ETHANOL ON MOTILITY OF THE SMALL INTESTINE. *(E.)* Robles, E. A.; Mezey, E.; Halsted, C. H.; Schuster, M. M. (Baltimore City Hosp., Md.). *Johns Hopkins Med. J.* 135(1):17-24, 1974.

Intestinal motility was measured before and after administration of alcohol in 13 male volunteers, aged 25-46 yr. These subjects consisted of 2 normal controls and 11 chronic alcoholics with no clinical evidence of cirrhosis, peripheral neuropathy, or other complicating disease. Jejunal motility measurements were made before and after ingestion of 0.8 g/kg ethanol in orange juice or injection of the same dose i.v. as a 20% solution in saline. Another study of jejunal motility was performed after ingestion of a mixture of urea (24.8 g), glycine (31.0 g), and alanine (36.8 g) dissolved in 300 ml orange juice which was isotonic to the ethanol solution. Ileal motility was measured before and after ingestion of the above dose of ethanol. Administration of ethanol inhibited Type I wave activity in the jejunum and augmented Type III wave activity in the ileum. Since ethanol equilibrates rapidly in most tissues and intraluminal concentrations reached in the jejunum are similar to blood ethanol concentrations, these effects were independent of the route of administration. The effect of ethanol on small intestine motility appears to be specific and not the result of fluid load or of hypertonicity, because administration of an equal volume of plain orange juice did not change motility and administration of an equivalent hypertonic solution of urea and amino acids produced a totally different response, consisting of a more rapid and complete suppression of Type I wave activity than was seen with ethanol and inhibition of Type III wave activity. It is suggested that ethanol-induced inhibition of Type I (impeding) waves in the jejunum and stimulation of Type III (propulsive) waves in the ileum may contribute to the diarrhea which develops in binge-drinking alcoholics. Although 7 of the 11 alcoholics tested had histories of diarrhea associated with binge drinking, they did not develop diarrhea in these tests. This may be attributed to the fact that the patients were fasted and studied in the supine position. It is also possible that the diarrhea associated with binge drinking is aggravated by congeners present in alcoholic beverages but not in ethanol.

5818 INCREASED DIAMINE OXIDASE ACTIVITY IN THE INTESTINAL LYMPH OF RATS ON FAT INGESTION. *(E.)* Wollin, A.; Jaques, L. B. (Univ. Saskatchewan Coll. Med., Saskatoon, Canada). *Can. J. Physiol. Pharmacol.* 52(3):760-762, 1974.

Diamine oxidase activity in the intestinal lymph of Wistar rats increased markedly shortly after p.o. administration of olive oil (2 ml/kg). This response was similar to that observed over a 4-hr period after i.p. injection of heparin (125 or 350 U/kg). Substitution of glucose solution (2 ml/kg) for olive oil did not produce this response. With repeated olive oil intubation on successive days, the enzyme activity levels became higher, reaching values on day 4 which were 6 times those of day 1. The increase was a combination of both higher lymph volumes and diamine oxidase activity per unit volume. When heparin and olive oil were administered together, an increase in diamine oxidase activity in the intestinal lymph was higher than the sum of the effects of separate treatments. It is suggested that the synergism may be related to the relatively unchanged lymph flow seen during heparin administration alone. Perhaps the combination treatment washed out more enzyme from the tissue because olive oil feeding increased lymph flow.

5819 NORADRENALINE IN THE GUINEA PIG ALIMENTARY CANAL: REGIONAL DISTRIBUTION AND SENSITIVITY TO DENERVATION AND RESERPINE. *(E.)* Juorio, A. V.; Gabella, G. (Dept. Anat., Univ. Coll. London, England). *J. Neurochem.* 22(5):851-858, 1974.

The concentrations of norepinephrine, dopamine, and 5-hydroxytryptamine were studied in the stomach, duodenum, ileum, cecum, colon, and rectum of the guinea pig. The wall of the alimentary canal was dissected into 2 fractions, one formed by the longitudinal muscle and myenteric plexus, the other formed by circular muscle, submucous plexus, submucosa, and mucosa. In the longitudinal muscle-myenteric plexus, the amount of norepinephrine was 0.56 μg/g fresh tissue in the ileum, 0.75 μg/g in the duodenum, 0.82 μg/g in the cecum, 0.85 μg/g in the stomach, 0.91 μg/g in the rectum, and 1.33 μg/g in the colon. The high value found in the colon was probably related to the occurrence of intramural adrenergic neurons. In the mucosa fraction, the concentration of norepinephrine increased steadily from 0.35 μg/g in the stomach to 0.72 μg/g in the rectum. The concentration of dopamine in the ileum was 0.06 μg/g for the longitudinal muscle-myenteric plexus and 0.07 μg/g for the mucosa component. The concentration of 5-hydroxytryptamine in the longitudinal muscle-myenteric plexus of the ileum was 0.11 μg/g, compared to 6.44 μg/g in the component containing mucosa. The highest value for 5-hydroxytryptamine in the mucosa component was found in the duodenum (30.1 μg/g) and there was a steady decrease through the small and large intestine. When extrinsic nerves to the ileum were damaged, the amount of norepinephrine in the corresponding ileal segment was reduced to less than 5% within 3 days in both fractions of the wall. 6-Hydroxydopamine (35 mg/kg i.v.) reduced to approximately 1/3 the amount of norepinephrine in longitudinal muscle-myenteric plexus of ileum and colon. Reserpine (1 mg/kg s.c. 72 hr earlier) reduced the amount of norepinephrine in longitudinal muscle-myenteric plexus of both ileum and colon to 0.01 μg/g. Doses of reserpine as small as 0.02 mg/kg were still effective in greatly reducing the norepinephrine concentrations. No difference in its effects on ileum and colon was observed.

5829 EFFECT OF VAGOTOMY ON POSTPRANDIAL GASTRIN LEVELS AND HEIDENHAIN POUCH SECRETION IN THE DOG. *(Ger.)* Becker, H. D.; Reeder, D. D.; Thompson, J. C. (Clin. Polyclin. Gen. Surg., Univ. Gottingen, Germany). *Dtsch. Med. Wochenschr.* 99(19):1023-1024, 1974.

Basal and postprandial serum gastrin levels and Heidenhain pouch acid secretion were measured in 6 dogs with Heinicke-Mikulicz pyloroplasty before and after selective proximal vagotomy, selective gastric vagotomy, and transthoracic truncal vagotomy. Each succeding form of vagotomy was performed at about 5 week intervals on all of the dogs. The mean basal serum gastrin concentration increased from 98 ± 2 pg/ml to 110 ± 5 pg/ml after selective proximal vagotomy and to 129 ± 8 pg/ml after selective gastric vagotomy. No further change occurred after transthoracic truncal vagotomy. All forms of vagotomy, particularly truncal vagotomy, increased postprandial serum gastrin concentrations. The increases in basal and postprandial serum gastrin levels probably result from higher pH in the antrum, but antral dilation resulting from stasis may also be involved. A significant increase (from 3.60 ± 0.50 to 5.38 ± 0.52 mEq/180 min) occurred in postprandial acid output from the denervated Heidenhain pouch after selective proximal vagotomy. Subsequent selective gastric vagotomy produced another increase to 7.15 ± 1.67 mEq/180 min. Transthoracic truncal vagotomy reduces the acid output to 4.97 ± 1.08 mEq/180 min, but this value is still significantly higher than control values. Since the Heidenhain pouch was denervated, these findings can only be accounted for by a humoral factor.

5830 GASTRIN RELEASE BY ETHANOL IN MAN AND IN DOGS. *(E.)* Becker, H. D.; Reeder, D. D.; Thompson, J. C. (Univ. Texas Med. Br., Galveston). *Ann. Surg.* 179(6):906-909, 1974.

Gastrin release by antral mucosa in response to ethanol and the effects of i.v. ethanol on basal serum gastrin concentrations were measured by radioimmunoassay in man and dogs. In 6 healthy young males, ingestion of 50% ethanol in water caused a significant increase from a basal serum gastrin level of 84 ± 5 pg/ml to a peak of 109 ± 4 pg/ml. With 18% ethanol, the peak serum gastrin concentration was significantly higher than basal. Ingestion of 50% ethanol also resulted in an integrated gastrin response, expressed in ng/ml/min, approximately 2.5 times greater than after ingestion of 18% ethanol. In man, a 60-min i.v. infusion of 7% ethanol (4 ml/kg/hr) caused a slight but significant increase of serum gastrin levels to 105 ± 9 pg/ml at 50 min. After infusion was stopped, serum gastrin fell to basal levels. In 5 adult mongrel dogs, perfusion of the antrum with 10% ethanol, pH 5.0, increased the serum gastrin in the antral venous outflow from 107± 6 pg/ml to 338 ± 48 pg/ml. Changing the perfusate to 10% ethanol, pH 1.0, significantly decreased the gastrin concentration (132 ± 20 pg/ml) after 30 min. I.v. infusion of 10% ethanol in dogs (10 ml/kg/hr for 2 hr) increased serum gastrin in antral venous outflow from 105 ± 4 pg/ml to 310 ± 26 pg/ml. Perfusion of the antrum with 0.1 N HCl decreased the antral venous gastrin to 147 ± 4 pg/ml. Thus, the gastrin response to alcohol ingestion is dependent on the mass of alcohol reaching the antrum, and acidification of the alcohol does not abolish its stimulatory effect. In dogs at least, the increase in serum gastrin levels induced by i.v. alcohol is caused by release of antral gastrin.

5831 VARIATION IN THE PATTERN OF CARBONIC ANHYDRASE ACTIVITY IN THE CELLS OF THE GASTRIC GLANDS. *(E.)* Winborn, W. B.; Seelig, Jr. L. L.; Girard, C. M. (Univ. Texas Health Sci. Ctr., San Antonio). *Histochemistry* 39(4):289-300, 1974.

Human gastric mucosa from patients undergoing gastric surgery and hamster gastric mucosa were examined under the electron microscope for carbonic anhydrase after incubation in Hansson's or Hausler's media. Tissues incubated in either media showed lead salt precipitates on the membrane system of the intracellular canaliculus of the parietal cells. However, discrete precipitates were observed within the granular endoplasmic reticulum of the chief cells and on the surface of parietal cell mitochondria only after incubation in Hansson's media. Enzyme activity was increased by betazole and inhibited by acetazolamide. The localization of carbonic anhydrase in the kidney, liver, RBC, and endothelial cells was similar to that observed by previous investigators with Hansson's media. This indicated that the reaction products in the gastric glands were the same as those seen in other tissues. The chief cells might be the main sources of carbonic anhydrase which eventually accumulates on the surface of the mitochondria on the membranes of the intracellular system. Although CO_2 is the product of carbonic anhydrase activity on carbonic acid and is probably formed within the mitochondria of parietal cells, only small amounts of reaction products were evident within the mitochondria. Thus, localization of the enzyme on the surface of the mitochondria may reflect the inability of the incubating media to penetrate the mitochondrial membranes. It is also possible that lead precipitates observed in the interior of chief and parietal cells are artifacts.

5832 EFFECT OF PENTAGASTRIN AND CARBACHOL ON ACID SECRETION IN THE SHAY RAT (PYLORUS-LIGATED RAT). *(Fr.)* Vagne, M.; Fargier, M. C.; Desvigne, A.; Chayvialle, J. A.; Lambert, R. (Edouard Herriot Hosp., Lyon, France). *Therapie* 28 (4):683-687, 1973.

Shay's technique was used to determine gastric response to pentagastrin (5-160 μg/kg s.c.) and carbachol (10-600 μg/kg s.c.) in female Sprague-Dawley rats. Controls received injections of physiological saline. Measurements were made 3 hr post-injection. With 80 μg/kg pentagastrin, the volume and acid output increased to 114% and 155%, resp., of control values. With 50 μg/kg carbachol, the volume was increased to 157%, the acid output to 164%, and the acid concentration to 126% [sic!] of control values. Supramaximal doses of carbachol (800 μg/kg) severely inhibited acid output so that it was essentially the same as in controls. It is stated that the increases found with pentagastrin were small and that those with carbachol showed clear augmentation.

5833 GASTRIC ACID SECRETION AND ULCEROGENESIS IN HISTAMINE-TREATED GUINEA PIGS. *(E.)* Hohnke, L. A. (Med. Res. Lab., Pfizer Inc., Groton, Conn.). *Gastroenterology* 66(6):1161-1167, 1974.

Gastric erosions were produced in guinea pigs by a single i.p. injection of histamine acid phosphate (5 mg/kg) and duodenal erosions by multiple i.m. injections (0.55 mg/kg every 30 min for 3-4 hr). Unlike gastric lesions, duodenal lesions were associated with a significant gastric output. The duodenal ulcer index and total acid output were proportional to the histamine dose; both parameters increased through 6 injections and subsequent injections had little additional effect. Ligating the pylorus eliminated formation of duodenal lesions indicating that contact of gastric juice with duodenal mucosa is a requirement for damage to the duodenum. Mepyramine and pyribenzamine (each 2 x 10 mg/kg i.p.) protected completely against gastric erosions, but this protective effect was accompanied by extensive duodenal damage. Buramimide (2 x 10 mg/kg) protected against duodenal lesions (56%) when injected intracardially but not i.p. Atropine (0.1 mg/kg i.p.) and carbenoxalone (100 mg/kg i.p.) protected 56% and 90% resp., against duodenal lesions. Neither atropine nor carbenoxalone caused any significant reduction in gastric acid output, suggesting that their protective effects are independent of their effect on gastric acid output, or that gastric acid is not primarily responsible for histamine-induced duodenal erosions in the guinea pig. Since carbenoxalone stimulates mucus output in man and rats, an enhanced mucus output in the duodenum may explain its protective effect against duodenal ulceration in guinea pigs. Lack of protection against gastric ulceration implies that the distribution of mucus-producing cells in the guinea pig differs from that in man and rat.

5834 THE EFFECT OF EXOGENOUS SECRETIN AND CHOLECYSTOKININ (CCK) ON PENTAGASTRIN-STIMULATED INTRINSIC FACTOR (IF) SECRETION IN MAN. *(E.)* Vatn, M. H.; Berstad, A.; Myren, J. (Ulleval Univ. Hosp., Oslo, Norway). *Scand J. Gastroenterol.* 9(3):313-317, 1974.

The secretion of gastric intrinsic factor was examined in 6 healthy subjects during i.v. infusion of pentagastrin (1 μg/kg/hr) alone or in combination with secretin (2 U/kg/hr) or 20% cholecystokinin (2 U/kg/hr). Cholecystokinin caused a reduction of intrinsic factor, acid, and pepsin output, but the last was not statistically significant. Secretin caused a significant reduction of acid and augmentation of pepsin output, whereas the output of intrinsic factor was unchanged. The findings suggest that secretin has a different effect on the secretion of the 3 components of gastric juice: intrinsic factor, acid, and pepsin.

5835 PREVENTIVE EFFECT OF FUSARIC ACID, A DOPAMINE β-HYDROXYLASE INHIBITOR, ON THE GASTRIC ULCERATION INDUCED BY WATER-IMMERSION STRESS IN RATS. *(E.)* Osumi, Y.; Takaori, S.; Fujiwara, M. (Fac. Med., Kyoto Univ., Japan). *Jap. J. Pharmacol.* 23(6):904-906, 1973.

The effect of fusaric acid (5-butylpicolinic acid) on gastric ulceration induced by immersing Wistar rats in water was studied with speical reference to brain norepinephrine and dopamine. Pretreatment of rats with 100 mg/kg fusaric acid i.p. 1.5 hr prior to immersion for 3 hr almost completely prevented the formation of gastric ulcer; the ulcer index was only 0.5 ± 0.3. The brain norepinephrine content in these animals did not differ significantly from that of nonstressed rats treated with the same dose of fusaric acid 4.5 hr before sacrifice. Intraventricular administration of fusaric acid (0.5 mg/animal) also prevented gastric ulceration: the ulcer index for these rats was 1.7 ± 0.4 compared with 3.6 ± 0.3 for controls. In contrast, tetrabenazine (50 mg/kg i.p., 30 min prior to stress) aggravated the gastric ulcer (ulcer index 4.4 ± 0.4). Brain norepinephrine and dopamine levels in these rats decreased to 9 and 4% of the control, resp., with increased release of these catecholamines. The results suggest that prevention of gastric stress ulcer by fusaric acid is due to decreased release of norepinephrine in the central nervous system.

5836 PURE HUMAN BIG GASTRIN. IMMUNOCHEMICAL PROPERTIES, DISAPPEARANCE HALF TIME, AND ACID-STIMULATING ACTION IN DOGS. *(E.)* Walsh, J. H.; Debas, H. T.; Grossman, M. I. (VA Wadsworth Hosp. Ctr., Los Angeles, Calif.). *J. Clin. Invest.* 54(2): 477-485, 1974.

Biological properties of pure natural human big gastrin (containing 34 amino acid residues) were compared with those of pure natural heptadecapeptide gastrins (with 17) from human and porcine sources. Radioimmunoassay inhibition curves indicated that natural gastrin was nearly 1.5 times more potent than big gastrin with the antibody used in this study. This difference was confirmed by demonstration of increased immunoreactivity generated when big gastrin was converted to natural gastrin by trypsinization. When infused i.v. into 4 dogs with gastric fistulas and Heidenhain pouches in equimolar doses, big gastrin produced slightly higher acid secretory responses. Responses to sulfated and nonsulfated forms were not significantly different, nor were responses to human and porcine natural gastrin. During infusion of equimolar doses, steady-state serum gastrin concentrations were more than 5-fold higher with big gastrin than with natural gastrin. The difference in steady-state blood concentrations could be accounted for by a corresponding difference in removal rates. The half times of the big gastrin preparations averaged 15.8 min while the half times of the natural gastrin preparations averaged 3.2 min. The calculated spaces of distribution for the 2 compounds were similar, about 25% of body weight. When the increment in serum gastrin was plotted against acid secretory response, it was found that nearly 5 times greater increments in molar concentrations of big gastrin than of natural gastrin were required to produce the same rate of acid secretion. The potency of these two molecular forms of gastrin can be expressed in two different ways. Based on exogenous molar doses, the potencies of the 2 gastrins were similar. However, based on molar increments in serum gastrin concentration, natural gastrin was approximately 5 times more potent than big gastrin. Hence, fractionation of these gastrin components may be important in estimating the acid-stimulating action represented by total serum gastrin as measured by radioimmunoassay.

5837 ACID RESPONSE TO GRADED DOSES OF PENTAGASTRIN AND FEEDING, AND EFFECT OF ATROPINE IN HEIDENHAIN POUCH CATS. *(E.)* Svensson, S.-O.; Emas, S. (Dept. Surg., Univ. Lund, Malmo, Sweden). *Scand. J. Gastroenterol.* 9(3):281-286, 1974.

In cats with both gastric fistulas and Heidenhain pouches, the maximum of the dose-response curve for Heidenhain pouch acid output (gastric fistula closed) to graded doses of i.v. pentagastrin was higher than that to graded meat meals. The maximal response to feeding was 70% of that to pentagastrin. Administration of atropine (0.1 mg/kg, i.v.) prior to stimulation with pentagastrin or meat markedly reduced the maximal response to feeding but did not alter the same level of response to pentagastrin. This could mean that endogenous gastrin was more susceptible than pentagastrin to inhibition by atropine at the parietal cells, or that atropine inhibited the release of gastrin, or both. The Heidenhain pouch acid response to 2-deoxy-D-glucose (100 mg/kg, i.v. gastric fistula open) amounted to 1/5-1/6 of the maximal response to feeding (gastric fistula closed), suggesting that feeding released more gastrin than vagal stimulation with 2-deoxy-D-glucose alone. Since treatment of peptic ulcer patients with optimal doses of 1-hyoscyamine had previously been shown to reduce the peak acid response to pentagastrin by about 30%, it is suggested that, on the basis of results of the present study, treatment of patients with anticholinergic drugs might more effectively reduce acid secretion in response to a meal than to pentagastrin.

5838 THE EFFECT ON THE STOMACH TISSUE OF REGIONAL STOMACH PERFUSION WITH DAUNOMYCIN. *(E.)* Fischerman, K.; Olsen, J. (Rigshosp., Copenhagen, Denmark). *Acta. Chir. Scand.* 140(2):143-146, 1974.

Healing of a gastroenteroanastomosis in pigs, performed after extracorporeal gastric perfusion with daunomycin, has been investigated, along with the effect on the tissue of retention of the drug in the stomach. The *in vivo* perfusion with daunomycin (2 mg/kg) was carried out on 8 animals for a period of 30 min. The outflow was allowed to proceed unimpeded in 4 of the animals, while in 2 it was arbitrarily occluded for 3 min and in the remaining 2, for 5 min. In one control animal, perfused without daunomycin, the outflow was occluded for 5 min. The perfused areas were then stained blue by addition of T 1824 to the perfusate. Finally, gastroenteroanastomosis was carried out on each animal. No macroscopic changes in the mucosa were seen when the outflow of the drug perfusate was unimpeded. Small ulcerations appeared in the mucosa of animals in which the outflow was occluded for 3 min; large ulcerations, when the outflow was occluded for 5 min. No perforation of the stomach wall was seen, however, and all gastroenteroanastomoses were healed in 14 days after the operation. No changes in the gastric mucosa appeared in the control animal. These results indicate that temporary occlusion of the outflow during stomach perfusion can be used in the treatment of inoperable cases of carcinoma of the stomach with the object of necrotizing large tumor areas. This technique may also be used as an initial treatment with cancer chemotherapeutic agents in connection with palliative stomach resection, without the risk of incomplete healing of gastroenteroanastomoses in the perfused areas.

5839 INDUCTION OF AUTOALLERGIC GASTRITIS IN DOGS. *(E.)* Porteous, J. R.; Fisher, J. M.; Lewin, K. J.; Taylor, K. B. (Stanford Univ. Med. Ctr., Calif.). *J. Pathol.* 112(3):139-146, 1974.

An attempt was made to develop a functional experimental model of autoallergic gastritis. Test dogs were injected (intradermally, s.c., or i.m.) with either a homologous preparation of gastric juice or gastric mucosa, emulsified with Freund's adjuvent. Of the 4 dogs receiving the gastric mucosal antigen, 2 demonstrated a significant decrease in acid output from Heidenhain pouches following maximal stimulation with histamine. Sera from one of the dogs formed precipitin lines against the antigen on immunodiffusion. Neither of these features was demonstrated by the control dogs or those immunized with gastric juice preparation. Neither were antibodies found in sera tested by immunofluorescence and complement fixation. There was no significant histologic difference between control and test dogs, and the histologic findings did not correlate with the functional studies. These findings indicate the need to establish a representative histologic base line prior to any attempts at production of autoallergic gastritis. It is suggested that parenteral immunization with a gastric mucosal homogenate produces decreased acid output probably *via* an immunological mechanism.

5840 INHIBITION OF PENTAGASTRIN-INDUCED GASTRIC ACID SECRETION IN MAN BY INTRAJEJUNAL GLUCOSE ADMINISTRATION. *(E.)* Christiansen, J.; Hendel, L. (Glostrup Hosp., Copenhagen, Denmark). *Acta Chir. Scand.* 140(3):246-248, 1974.

The effect on gastric acid secretion of intrajejunal instillation of hyperosmolar glucose was studied in 5 healthy male subjects. After a 90 min stimulation with a submaximal dose of pentagastrin (0.5 ug/kg/hr), 100 ml of 50% glucose was administered through a jejunal tube over a 5 min period. In all subjects, steady-state secretion was obtained after 45 min of pentagastrin stimulation. A new and lower secretory plateau was reached after intrajejunal instillation of glucose. Mean acid output during steady-state secretion was reduced 71%, from 8.5 to 2.2 mEq/15 min. Intrajejunal administration of hyperosmolar glucose markedly depressed the secretory volume as well as the acidity on the average of 66% and 68%, resp. Thus, intrajejunal instillation of hyperosmolar glucose inhibited gastric acid secretion significantly. The reduction in secretory volume proves this inhibition cannot be ascribed to reflux from the duodenum. Whether the acid-inhibitory action of glucose instillation is mediated by release of gut-glucagon or by some other intestinal hormone or combination of hormones is not certain. This study has demonstrated a jejunal acid inhibitory mechanism of probably the same magnitude as the duodenal inhibitory mechanism. The findings emphasize the role of gastric acid hypersecretion as a cause of peptic ulcer and malabsorption in patients who have undergone massive small bowel resection or bypass.

5841 INFLUENCE OF PARATHYROID HORMONE AND VITAMIN D ON BASAL GASTRIC SECRETION IN RATS. *(E.)* Ohrn, P. G.; Frenning, B.; Hessman, Y.; Johansson, H.; Segerstrom, A. (Univ. Hosp., Uppsala, Sweden). *Scand. J. Gastroenterol.* 9(3):275-279, 1974.

The effect of parathyroid hormone on basal gastric secretion of hydrochloric acid and mucus was compared with that of vitamin D during a 14-day period of treatment on 10 male Sprague-Dawley rates prepared with chronic gastric fistulae. Parathyroid hormone (40 U/100 g s.c.) induced an increase in serum calcium level after 1 week and a further increase after 2 weeks. No change in serum calcium was observed after 1 week of vitamin D treatment (36,000 IU/100 g s.c.) but the levels were increased after a further 7 days. After 14 days the parathyroid hormone and vitamin D treatments induced similar decreases in gastric secretory rate. However, the acidity diminished to a greater degree in vitamin D-treated rats, possibly because the serum calcium level became more elevated in vitamin D-treated rats after 14 days. This result may indicate that acidity is more dependent on the serum calcium level than is the gastric secretory rate. The hydrogen ion concentration in gastric juice from parathyroid hormone-treated rats did not differ from pretreatment values, but was slightly lower than recorded in the control group receiving saline. Chloride ion concentration and fucose concentration were independent of parathyroid hormone or vitamin D or saline. Mean concentration of total sialic acid in parathyroid hormone-treated rats did not differ from pretreatment levels, but consecutive reductions were found in saline-treated controls. After 1 week of vitamin D treatment, a minor increase was noted in the total sialic acid concentration. The relation between free and total sialic acid did not change during treatments. These results appear to exclude an increased concentration of hydrogen ions in the gastric juice as a cause of gastric ulcers in hyperparathyroid rats.

5842 Penicillium viridicatum MYCOTOXICOSIS IN THE RAT. III. HEPATIC AND GASTRIC LESIONS. *(E.)* McCracken, M. D.; Carlton, W. W.; Tuite, J. (Sch. Vet. Sci. Med., Purdue Univ., West Lafayette, Ind.). *Food Cosmet. Toxicol.* 12(1):99-105, 1974.

Hepatic and gastric lesions developed in male rats fed grain cultures and fungal mats of *Penicillium viridicatum.* In the present experiment, the progression of hepatic changes was followed in rats fed a rice culture of the fungus at a dietary concentration of 25%. Initial lesions consisted of edema of the portal areas and pericholangitis, and were followed by hypertrophy and hyperplasia of the biliary epithelium, periductal fibrosis, and focal areas of hepatic cell necrosis. Later lesions were necrotizing cholangitis, stenosis, and obliteration of biliary ducts. A severe necrotizing cholangiohepatitis developed in rats fed fungal mats of *P. viridicatum.* Gastric erosions occurred in the fundic mucosa, and some rats developed a necrotizing cellulitis of the gastric submucosa apparently unrelated to the erosions. The toxin(s) elaborated by this isolate of *P. viridicatum* induced a unique spectrum of lesions, and it is proposed that the pathological alterations were the result of blood-borne toxin(s). In addition to producing ocular and hepatic lesions, the toxic principle in grain cultures and fungal mats appeared to have a predilection for the vessels in the loose connective tissue in several locations, such as the scrotum, gastric submucosa, and body subcutis.

5843 HIGH ENERGY PHOSPHATE COMPOUNDS OF GASTRIC TISSUE IN RATS. *(E.)* Kowalewski, K. (Surg. Med. Res. Inst., Univ. Alberta, Edmonton, Canada). *Arch. Int. Physiol. Biochim.* 82(1):1-6, 1974.

The content of ATP, ADP, and AMP in the resting and secreting mammalian stomach *in vivo* was studied in gastric fistula of male Wistar rats. The rats were divided into 4 groups. Group 1 was infused *via* the vena cava with normal saline; group 2 was similarly infused with histamine in saline; group 3 was fasted for 24 hr with no infusion; and group 4 was fasted 24 hr with no infusion, then fed 30 g corned beef/kg body weight. Compared with saline infused controls, animals stimulated with histamine had a significant increase in HCl and pepsin outputs. After 24 hr of saline or histamine infusion, the rats were sacrificed, their stomachs were separated into the glandular part and rumen, and the different types of tissues were analyzed for ATP, ADP, and AMP. Similar tests were carried out on stomachs of animals not infused. The ranges of values within each group in the study showed very great variation from one stomach to another. No significant correlation was found between the fasting, postprandial, or posthistamine state of the stomach and the concentrations of high-energy phosphates in gastric tissues. The study thus failed to demonstrate that high energy phosphates, and particularly ATP, are a possible source of energy necessary for the production of H^{+}.

SECRETION AND METABOLISM

Pancreas

5847 EFFECT OF HEPARIN ON PANCREATIC FUNCTION IN THE DOG. *(Ger.)* von Nowak, W.; Sill, U.; Lippert, H.; Hommel, H.; Fischer, U. (Surg. Clin. Polyclin., Ernst Moritz Arndt Univ., Greifswald, Germany). *Z. Gesamte Inn. Med.* 29(6):250-252, 1974.

In vivo experiments were performed on dogs to determine whether increases in pancreatic or biliary secretion are responsible for increases in the volume of duodenal contents and their bicarbonate concentrations found after injection of heparin. Both under basal conditions and during infusion of secretin (0.25 U/kg/min), heparin (200 IU/kg i.v.) first increased and then decreased pancreatic secretion, but these changes were not significant. Between 15 and 30 min after heparin injection significant increases did occur in the volume of the duodenal contents and its bilirubin concentration. It is concluded that heparin causes an increase in the volume of the duodenal contents by increasing bile flow rather than exocrine pancreatic secretion. Administration of 100 IU/kg heparin i.v. inhibited both basal and glucose-induced insulin secretion in dogs.

5848 EFFECTS OF INTRAGASTRIC AND INTRADUODENAL ETHANOL ON CANINE EXOCRINE PANCREATIC SECRETION. *(E.)* Tiscornia, O. M.; Gullo, L.; Sarles, H.; Mott, C. B.; Brasca, A.; Devau, M. A.; Palasciano, G.; Hage, G. (Res. Unit Dig. Dis., INSERM, Marseille, France). *Digestion* 10(1):52-60, 1974.

The effects of intragastric or intraduodenal instillation of ethanol on exocrine pancreatic secretion were assessed in 9 mongrel dogs provided with pancreatic and gastric fistulae (Thomas cannula) and submitted to a continous i.v. injection of secretin (1.0 U/kg hr). The experiments were carried out on the same group of dogs either in the conscious state or under very light halothane anesthesia. Intragastric instillation of ethanol (1.0 g/kg) in anesthetized dogs resulted in significant increases in: bicarbonate output and flow rate comparable to 1/4 of the effect produced by secretin administration; and in protein concentration and output similar to 1/3 of the effect due to secretin with added cholecystokinin injection. Intraduodenal ethanol (0.7 g/kg) changed protein concentration significantly in anesthetized dogs but did not induce any significant modification in conscious animals. Intraduodenal HCl (2.5 mM) at the end of the ethanol infusion revealed that the intestinal mucosa was still able to release secretin and cholecystokinin. It is concluded that p.o. ethanol stimulates pancreatic secretion only when the stomach is present and able to secrete HCl and when it can evacuate its contents into the duodenum. In humans, there is a moderate but significant increase in bicarbonate output after intraduodenal ethanol infusion. This effect did not occur in the dogs.

5849 GASTRIC ACID DOES DRIVE PANCREATIC BICARBONATE SECRETION. *(E.)* Grossman, M. I.; Konturek, S. J. (VA Wadsworth Hosp. Ctr., Los Angeles, Calif.). *Scand. J. Gastroenterol.* 9(3):299-302, 1974.

Earlier studies questioned whether the amount of acid in the duodenum after meals was great enough to stimulate pancreatic secretion. In this study, in dogs with gastric and pancreatic fistulas, a meal of liver was instilled into the gastric fistula, and the pH of the gastric contents was held constant at various levels by continuous intragastric titration. With intragastric pH held at 7.0, pancreatic bicarbonate secretion was low and protein secretion moderate,characteristic of the response to cholecystokinin alone. No augmentation of pancreatic bicarbonate secretion occurred as intragastric pH was lowered from 7.0 to 4.5. Between pH 4.5 and 3.0 bicarbonate secretion rose sharply in response to increasing acidification. Bicarbonate secretion was already near maximal at pH 3.0 and so showed little further increase as pH was lowered to 1.5. Augmentation of pancreatic protein secretion occurred in the same range of pH that caused bicarbonate responses. With a meal held at pH 5.0 by intragastric titration, about 0.4 U/kg/hr of exogenous secretin produced bicarbonate and protein responses equal to those of a natural meal. It is concluded that gastric acid plays a major role in driving pancreatic secretion. The small amount of secretin released is highly effective because of the amplifying effect of cholecystokinin released by other constituents of the meal.

5850 EFFECT OF CARBACHOL ON AMINO ACID INCORPORATION INTO PROTEIN OF RAT PANCREAS In Vitro.

(E.) Irwin, C.; Tenenhouse, A. (Dept. Pharmacol. Therap., McGill Univ., Montreal, Canada). *Can. J. Physiol. Pharmacol.* 52(3):632-640, 1974.

The effect of various cholinergic drugs on incorporation of ^{3}H-leucine into protein of rat pancreas *in vitro* was studied. Carbachol (10^{-5} M) and bethanechol (10^{-4} M), but not pilocarpine, inhibited incorporation 70-80%. Even in the continued presence of carbachol, the rate of incorporation is depressed only 40-60 min. It recovers and eventually exceeds that seen in untreated tissue. After 4 hr incubation the amount of ^{3}H-leucine incorporated into protein is the same in carbachol-treated and untreated tissue. The alteration of amino acid incorporation can be dissociated from the effect of the drug on secretion in several ways: (1) calcium deprivation abolishes carbachol-stimulated secretion but not the inhibition of amino acid incorporation; (2) atropine, 10^{-8} M, totally abolishes the effect of carbachol on amino acid incorporation without affecting secretion (10^{-5} M atropine is needed to abolish carbachol stimulated secretion); (3) pilocarpine stimulates secretion but has no effect on amino acid incorporation. The inhibition of amino acid incorporation is not due to inhibition of amino acid transport nor to a decrease in tissue ATP concentration. It is concluded that there is no clear relation between protein secretion and synthesis. Muscarinic agents, which stimulate secretion of protein, may also cause changes in the rate of amino acid incorporation into protein; however, the changes observed will depend on when, after administration of the secretagogue, protein synthesis is measured.

5851 HISTOLOGICAL FINDINGS AND AMYLASE CONTENTS OF THE PANCREAS AND PAROTID GLAND OF RATS WITH EXPERIMENTAL OBSTRUCTION OF THE COMMON BILE DUCT.

(E.) Kakizaki, G.; Saito, T.; Soeno, T.; Fujiwara, Y.; Ohizumi, T.; Sasahara, M.; Yamazaki, M.; Nihei, T.; Ishidate, T.; Senoo, A. (Akita Univ. Sch. Med., Japan). *Tohoku J. Exp. Med.* 112(1):79-88, 1974.

In 9 Wistar rats the common bile duct was ligated at the hepatic hilus (superior to the site of inflow of the pancreatic duct). After 96 hr histological changes in the pancreas and parotid were studied and compared with findings for 10 control rats. Amylase activity was measured in both organs and in serum. In animals with common bile duct obstruction, the pancreas contained somewhat fewer zymogen granules and fine granular fat droplets in the glandular acinar cells. Round cell infiltration was noted occasionally in the coarse connective tissue outside the pancreatic parenchyma. Histologically, the parotid in rats with biliary obstruction was similar to the normal gland; the only abnormality was fat droplets in the glandular acinus. Pancreatic amylase activity was decreased after common bile duct obstruction, but parotid amylase was normal. Serum amylase was decreased in the obstruction group. These results indicate that common bile duct obstruction does not significantly affect the histology and function of the parotid gland.

5852 INFLUENCE OF BILE DUCT LIGATION ON EXOCRINE PANCREATIC SECRETORY ACTIVITY IN THE RAT.

(E.) Geratz, J. D.; Lamb, J. C. IV (Univ. North Carolina Sch. Med., Chapel Hill). *Am. J. Physiol.* 227(1):119-122, 1974.

Ligation of the proximal common bile duct in the anesthetized rat led to a marked decrease in spontaneous and trypsin inhibitor-induced secretion of pancreatic amylase as judged by the amount of enzyme in the small intestine. The reduction in output was not influenced by feeding rat bile or sodium taurocholate solution, showing that the reduced enzyme output in ligated animals is not due to absence of bile acids or other bile constituents from the intestine. To determine whether increased intrabiliary pressure caused by the bile duct occlusion was indirectly responsible for the altered pancreatic response, rats were furnished with a cannula proximal to the ligature and draining to the outside. This procedure led to a rise in spontaneous amylase secretion and an additional stimulation of enzyme release when trypsin inhibitor was administered. These differences were not large, however, and were not significant at the 5% level. When biliary-pancreatic secretions were collected from a distal bile duct fistula, the amylase output showed a 1.5-fold increase over a 3 hr period. In rats where such a fistula was combined with a proximal bile duct ligature, there was a 50% fall rather than a rise in amylase secretion.collected from the distal bile duct fistula. Presence of a fistula proximal to the ligature or of a bypass around the ligature prevented the decline in enzyme levels in this fistula, but did not produce the hypersecretory state seen in the ligature-free rats. Perfusion of bile or Ringer solution through the duct distal to the ligature did not significantly raise the depressed secretion values. The results thus showed that the release of enzyme by the rat pancreas was affected by the location of a bile duct ligature. None of several possible explanations for the phenomenon was substantiated.

5853 ZINC DEFICIENCY AND DECREASED PANCREATIC SECRETORY RESPONSE.

(E.) Sullivan, J. F.; Burch, R. E.; Quigley, H. J.; Magee, D. F. (VA Hosp., Omaha, Neb.) *Am. J. Physiol.* 227(1):105-108, 1974.

Since low serum zinc concentrations and pancreatic abnormalities are common in cirrhosis, a study was carried out to evaluate the effect of dietary zinc deficiency on pancreatic secretory mechanisms. Pancreatic juice was obtained by cannulating the pancreatic ducts of 10 pigs fed a zinc-deficient diet for 6 weeks. Five of the animals received zinc supplementation (120 μg/g diet) throughout the study and served as controls. I.v. infusion of secretin (0.25 U/min in 2 ml physiological saline) caused a decrease in the volume of pancreatic juice secreted by zinc-deficient pigs. This pancreatic juice contained reduced concentrations of magnesium and calcium and decreased protease and amylase activity. Zinc was not detectable in pancreatic juice following secretin stimulation in either control or zinc-deficient pigs. When vagal stimulation, i.v. cerulein injection, or gastric infusion were each combined with a secretin infusion, increases in zinc, calcium, magnesium, protease, and amylase resulted, but the increases were smaller in the zinc-deficient animals than in the controls. Histologically, the acinar tissue from zinc-deficient pig pancreas revealed decreased granularity and decreased cytoplasm. Histochemical staining revealed no appreciable difference in pancreatic malic dehydrogenase, lactic dehydrogenase, NADH diaphorase, alkaline phosphatase, or alcohol dehydrogenase (all of which are zinc metalloenzymes) in control and zinc-deficient pigs. Trace metal analysis of pancreatic tissue revealed significantly decreased zinc levels associated with zinc deficiency, but the calcium and magnesium contents were not significantly different from control values. The mechanism by which zinc deficiency diminishes pancreatic secretory response to known secretagogues is unexplained.

5854 METHADONE-INDUCED INHIBITION OF CENTRAL VAGAL PANCREATIC STIMULATION PRODUCED BY 2-DEOXY-D-GLUCOSE. *(Fr.)* Vaille, C.; Roze, C.; de La Tour, J.; Souchard, M; Debray, C. (Bichat Hosp., Paris, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 278:2839-2841, 1974.

Pancreatic secretion was investigated in 2 groups of anesthetized male Wistar CF rats with pancreatic and biliary fistulas before and after injection with (1) large doses of 2-deoxy-D-glucose (25 mg i.v.) or (2) methadone (5 mg/kg s.c.) followed, 5 min later, by 2-deoxy-D-glucose (25 mg i.v.). The effect of 2-deoxy-D-glucose on pancreatic secretion reached a maximum 1-1.5 hr after injection when the output of water was increased by about 2.5 fold, the amylase concentration 3-fold, and the total protein concentration 3.5-fold. The outputs of amylase and total protein were increased 8- to 10-fold. When methadone was administered first, pancreatic stimulation induced by 2-deoxy-D-glucose was completly blocked but basal pancreatic secretion remained unchanged, as was verified in rats given methadone alone. The blocking effect of methadone on vagal pancreatic stimulation induced by 2-deoxy-D-glucose is similar to the effect of desipramine on gastric secretion stimulated by 2-deoxy-D-glucose in the dog and the effects of desipramine and morphine on gastric secretion in pylorus-ligated rats. Since these compounds are much more active when injected i.v., they probably act on the central nervous system. The effect of methadone is not due to peripheral blocking of cholinergic receptors, because preliminary experiments indicate that the effect of exogenous acetylcholine on pancreatic secretion is unaffected by methadone.

5855 STIMULATION OF DNA SYNTHESIS IN MOUSE PANCREAS BY TRIIODOTHYRONINE AND GLUCAGON. *(E.)* Malamud, D.; Perrin, L. (Massachusetts Gen. Hosp., Boston). *Endocrinology* 94(4):1157-1161, 1974.

A single s.c. or i.p. injection of triiodothyronine (20 μg) and glucagon (200 μg) stimulated growth of liver, kidney, and pancreatic tissue in Charles River mice. The greatest stimulation of cell proliferation, as evaluated by DNA specific activity, occurred in the pancreas. When the hormones were given s.c., there was also marked stimulation of DNA synthesis in the liver. Pancreatic hyperplasia was confined to the cells of the exocrine pancreas. In liver, both hepatocytes and Kupffer cells demonstrated increased labeling with ^{3}H-thymidine. Cellular hypertrophy, as measured by the ratio of RNA to DNA, was increased in liver and kidney. Triiodothyronine and glucagon produced about equal and additive increases in ^{3}H-thymidine incorporation into pancreatic DNA. The present system should be useful for studying factors controlling pancreatic growth.

5862 RAPID TRANSFER OF FOLIC ACID FROM BLOOD TO BILE IN MAN, AND ITS CONVERSION INTO FOLATE COENZYMES AND INTO A PTEROYLGUTAMATE WITH LITTLE BIOLOGICAL ACTIVITY.

(E.) Lavoie, A.; Cooper, B. A. (Royal Victoria Hosp., Montreal, Quebec Canada). *Clin. Sci. Mol. Med.* 46(6): 729-741, 1974.

^{3}H- folic acid infused i.v. into 9 patients (42 to 72 yr) with bilary fistulae appeared promptly in the bile, coincident with ^{131}I-labeled Rose Bengal injected simultaneously. The radioactivity was distributed among several fractions of biological folates present in bile in association with folic acid and with an unidentified folate which chromatographed on DEAE-Sephadex close to 10-formyltetrahydrofolyl monoglutamate. Based on the affinity for DEAE-Sephadex and the support of growth of *Lactobacillus casei, Streptococcus fecalis* and *Pediococcus cerevisiae*, some folates of human bile were identified as 10-formyltetrahydrofolate, 10-formylfolate, 5-formyltetrahydrofolate, 5-methyltetrahydrofolate and tetrahydrofolate or 5,10-methylene tetrahydrofolate. After infusion of folic acid, the formyltetrahydrofolates increased more rapidly than did the 5-methyltetrahydrofolate. The unidentified radioactive folate contained both the pteridine and *p*-aminobenzoate portions of folate. It did not appear to support growth of the test microorganisms and did not seem to be bound to a protein or a chain of γ-glutamates. This unidentified radioactive folate was present in the bile of a dog injected with ^{3}H-folic acid but was absent from extracts of liver; it may be a transport form of folate or a special modification imposed on folic acid during transport across the liver. When folic acid was presented to the liver after i.v. infusion in doses similar to the folate content of a high folate meal, some was rapidly cleared across the liver into the bile at a rate similar to the clearance of Rose Bengal. Apparently biologically active folate was flushed from the hepatic cells into the bile. The small recovery of radioactive folate coenzymes during the period of collection indicates that most of the folic acid presented to the liver entered the intracellular folate pools and was diluted by endogenous nonradioactive folate.

5863 ENERGY REQUIREMENT IN REGENERATIVE AND ATROPHIC PROCESSES OF THE LIVER IN MAN AND OTHER MAMMALS.

(E.) Yamaoka, Y.; Ohsawa, T.; Takasan, H.; Ozawa, K.; Honjo, I. (Kyoto Univ. Fac. Med., Japan). *Surg. Gynecol. Obstet.* 139(2): 234-240, 1974.

Mitochondrial metabolism in liver regeneration and atrophy processes was studied in adult male Wistar rats, mongrel dogs of both sexes, *Macaca irus* monkeys, and humans. Liver specimens were obtained from patients at laparotomy for stomach cancer and hepatic carcinoma localized in another lobe. In animals, fluctuations of portal blood flow were produced by ligation of portal vein branches and by partial hepatectomy. All animals received 50 μCi/kg i.v. injections of methyl-^{3}H thymidine 1 hr prior to sacrifice for analysis of DNA synthesis. With excess portal blood supply, the phosphorylative activity/U of cytochrome a (+ a_3) increased to approximately 45 times/sec from control levels of 25 times/sec. Such enhancement was probably a requisite for the increased nuclear DNA synthesis that followed. Conversely, inhibition of mitochondrial hyperfunction with decreased portal flow prevented a rise in DNA synthesis. In addition, regenerative ability in mammalian livers declined in parallel with decreasing contents of respiratory enzymes in the mitochondria. In rats, rabbits, dogs, and monkeys, which have considerably larger amounts of such enzymes than those found in humans (e.g., respiratory enzymes were 3 times greater in rat liver than in human liver), the enzyme content remained unchanged during regeneration, while in regenerating human livers, amounts increased remarkably. The results indicate that in all mammalian livers there is a clear relation between portal blood supply and mitochondrial phosphorylative activities. Furthermore, these findings show that the expression of phosphorylative activity/U of cytochrome a (+ a_3) is useful since even with changed levels of respiratory enzymes found in various liver diseases, enhancement of activity is encountered more frequently in patients with an increased metabolic overload on the liver. Also, increased activity plays an important role in homeostasis for generation of energy in damaged livers.

5864 STUDIES ON THE DECREASE IN BILE FLOW PRODUCED BY SULFOBROMOPHTHALEIN.

(E.) Schulze, P. J.; Czok, G. (Inst. Pharmacol., Univ. Hamburg, Germany). *Toxicol. Appl. Pharmacol.* 28(3): 406-417, 1974.

A reduction in bile flow resulted when urethane-anesthetized male Wistar rats were infused with 1.875 mg/min BSP i.v. The infusion times at which a 50% decrease in bile flow occurred were almost the same in bile salt-depleted animals (biliary fistula for 5 hr) and in those given taurocholate (150 nM/100 g/min) during the depletion; but both infusion times were significantly lower than those observed in nondepleted rats. While the overall excretion of the dye was mainly dependent on the BSP-glutathione (GSH) fraction in the bile, the reduction in bile flow was inversely related to the amount of BSP-GSH conjugate excreted and the hepatic GSH concentrations before the infusion. A marked fall in hepatic GSH was observed after prolonged urethane narcosis, indicating that the decrease in GSH during bile salt depletion was due mainly to the effect of anesthesia. Since the infusion of equimolar and larger amounts of BSP-GSH resulted in choleresis, it is concluded that the unconjugated BSP is responsible for the reduced bile flow during BSP infusion. It is suggested that for BSP-GSH, in contrast to BSP, the rate-limiting step in the transport from blood to bile is not its biliary excretion, but its uptake by the liver.

5865 COLLAGEN PROLINE HYDROXYLASE ACTIVITY AND ^{35}S SULPHATE UPTAKE IN HUMAN LIVER BIOPSIES.

(E.) McGee, J. O'D.; Patrick, R. S.; Rodger, M. C.; Luty, C. M. (Roy. Infirm., Glasgow, Scotland). *Gut* 15(4):260-267, 1974.

To assess connective tissue biosynthetic activity in human liver disease, collagen proline hydroxylase (a key enzyme in collagen biosynthesis) and the uptake of ^{35}S sulfate (a precursor of sulfated mucopolysaccharides) were measured in hepatic tissue obtained mainly by percutaneous biopsy. A procedure is described for the quantitation of collagen proline hydroxylase in cryostat sections which allows for the simultaneous histopathological examination of the liver specimen. A 3- to 8-fold increase in the activity of this enzyme was found in 4 cirrhotic livers compared with the mean value of 4 normal livers and 2 biopsies from patients with Gilbert's syndrome. Elevated hydroxylase levels were found also in 5 patients with hepatic dysfunction but without cirrhosis (4 alcoholics and 1 patient with persistent hepatitis associated with serum smooth muscle antibody). It is suggested that the hepatic level of collagen proline hydroxylase may be a useful quantitative index of fibroblastic activity in human liver disease. Autoradiographic studies of radioactive sulfate uptake in biopsy specimens from patients with chronic liver disease showed an exaggerated incorporation of isotope not only at sites of established fibrogenesis but also in the walls of sinusoids throughout the liver.

5866 CYCLIC GUANOSINE 3', 5'-MONOPHOSPHATE AND GALLBLADDER CONTRACTION.

(E.) Amer, M. S. (Dept. Pharmacol., Mead Johnson Res. Ctr., Evansville, Ind.). *Gastroenterology* 67(2):333-337, 1974.

During investigation of the possible role of cyclic guanosine 3',5'-monophosphate (GMP) in smooth muscle contraction of the gallbladder, it was found that cholecystokinin (10^{-8} M), acetylcholine (10^{-4} M), and oxymetazoline (10^{-5} M) stimulated guanylyl cyclase activity in intact, isolated rabbit gallbladder. Cholecystokinin and acetylcholine also raised the intracellular levels of cyclic GMP in that tissue. This rise preceded and could mediate both the cholecystokinin- and acetylcholine-induced contractions. The role of cyclic GMP in mediating gallbladder contraction raises the possibility of its involvement in mediating contractions of other smooth muscles as well.

5867 EFFECT OF TYPES OF DIETARY FAT ON THE RAT LIVER. IV. FATTY LIVER.

(Pol.) Opuszynska, T. (Inst. Food Nutr., Warsaw, Poland). *Rocz. Panstw. Zakl. Hig.* 24(4):425-431, 1973.

Thaler's scale was used to evaluate the extent of fatty degeneration in livers from 444 male Wistar rats fed a diet for 4- or 15-week periods in which 38% of the calories were provided by fat. Fats were either unprocessed or had been heated for 30 min. at 180°C. They consisted of soybean oil, commercial rapeseed oil and experimental preparations low and high in erucic acid, Palma margarine, butter, and lard. Marked fatty degeneration of the liver was observed in all animals fed high-fat diets for 4 weeks, regardless of whether the fats were heated or not. Rapeseed oil produced more extensive and severe fatty changes than soybean oil. These changes became more pronounced after 15 weeks of feeding, especially in rats receiving rapeseed oil high in erucic acid. Margarine produced the least fatty change, and continuation of the high-fat diet for 15 weeks did not intensify these changes. Butter caused more severe fatty degeneration which became more pronounced after 15 weeks, particularly if the butter had been heated. Lard caused some degeneration in about 50% of the rats. Unheated lard caused severe degeneration in twice as many rats after 15 weeks than after 4 weeks, but heated lard had the same effect whether it was fed for 4 or 15 weeks.

5868 STUDIES ON THE REGULATION OF GLUTATHIONE LEVEL IN RAT LIVER.

(E.) Tateishi, N.; Higashi, T.; Shinya, S.; Naruse, A.; Sakamoto, Y. (Osaka Univ. Med. Sch., Japan). *J. Biochem. (Tokyo)* 75(1):93-103, 1974.

Starvation of male Donryu rats for 48 hr resulted in a decrease in liver glutathione content to between 2/3 and 1/2 the normal level. On refeeding, the hepatic glutathione content rapidly returned to normal, followed by a gradual increase in glucose-6-phosphate dehydrogenase (G6PD). Maintenance of the liver glutathione level was dependent on a food intake of 10 g/day. Actinomycin D (20 μg/100 g i.p.) inhibited the induction of G6PD but did not affect the increase in glutathione concentration. Cyclohexamine (25-200 μg/100 g i.p.) also failed to inhibit the increase occurring in hepatic glutathione on refeeding. Accordingly, recovery of the glutathione level after starvation does not require *de novo* formation of glutathione-synthesizing enzymes. The activities of enzymes involved in glutathione synthesis (γ-glutamylcysteine synthetase and glutathione synthetase) in the liver were similar in starved and refed rats. Hepatic cysteine and glutamate concentrations were reduced in starved animals and increased rapidly with refeeding. This may cause increased glutathione synthesis and can account quantitatively for the rapid rise of hepatic glutathione on refeeding. However, the concentration of adenine nucleotides was not favorable for glutathione synthesis in the early stage of refeeding; relatively higher concentrations of ADP and AMP were present, which could inhibit one or both of the reactions leading to glutathione synthesis. Glutathione degradation activity was lower in refed animals than in fasted ones. The turnover of hepatic glutathione was much faster in fasted than in refed rats. The degradation rate of glutathione is apparently involved in regulating the concentration of hepatic glutathione.

5869 ROUTE OF FLOW AND MICROPATHOLOGY RESULTING FROM RETROGRADE INTRABILIARY INJECTION OF INDIA INK AND FERRITIN IN EXPERIMENTAL ANIMALS. *(E.)* Bockman, D. E. (Med. Coll. Ohio, Toledo). *Gastroenterology* 67(2):324-332, 1974.

To investigate the route from the biliary system to the sinusoids, India ink (10% in saline or 8% in 4% gelatin), ferritin (10 mg/ml saline), or a mixture of both (10 mg ferritin/ml, 10% India ink) were injected into the common bile duct of mice, rats, and rabbits. All injections were performed with just enough pressure to cause retrograde flow. Tissue was prepared for light- and electron-microscopic study by routine techniques. Tracer material was fairly evenly distributed through the liver, filling many parts of the ductal system. India ink suspended in normal saline was found widely distributed in liver sinusoids. Electron microscopy showed that aggregates of platelets were sometimes associated with tracer material. Isolated small groups of hepatic cells contained dense deposits of India ink filling part or all of the cytoplasm. Marked cellular disruption was evident in electron micrographs of similar areas. It is concluded that retrograde intrabiliary injection of material disrupts hepatic cells to allow escape of tracers into sinusoids through the spaces of Disse. It is proposed that retrograde injection of such materials as radiocontrast media may cause similar micropathology and entry of biliary contents into the circulation. An understanding of this relation is especially important to predict the possible results of retrograde injections used in operative, percutaneous, and endoscopic cholangiography.

5870 EFFECT OF THE TYPE OF DIETARY FAT ON RAT LIVER. V. ALKALINE PHOSPHATASE IN THE SERUM AND LIVER. *(Pol.)* Opuszynska, T. (Inst. Food Nutr., Warsaw, Poland). *Rocz. Panstw. Zakl. Hig.* 24(5):597-603, 1973.

A high-fat diet, in which 38% of the calories were provided by fat, was fed to 6-week-old male Wistar rats for 4 or 15 weeks, and alkaline phosphatase activity was determined in their sera and liver homogenates. The fats consisted of heated and unheated soybean and rapeseed oils, Palma margarine, butter, and lard. Results were compared to those obtained from young controls. After 4 weeks of the high-fat diet, the mean serum alkaline phosphatase activity increased from 4.5 Bessey-Lowry U (controls) to 11.81 ± 1.46-15.50 ± 1.68 U for rats fed vegetable oils, 9.25 ± 2.33 U for rats fed margarine, and 11.35 ± 2.04 U for those fed lard. The mean serum alkaline phosphatase activity in rats fed butter was close to control values (6.66 ± 1.47 U). After 15 weeks the increase in activity was more pronounced: it was greatest in rats fed rapeseed oil high in erucic acid (21.03 ± 2.06 U). Soybean oil, rapeseed oil low in erucic acid, margarine, and heated butter caused smaller increases ranging from 9.53 ± 2.27 U to 15.06 ± 2.20 U. No increases were observed in rats receiving unheated butter, and only a slight increase occurred in those given lard. High-fat diets produced increases in liver alkaline phosphatase which were less pronounced than those occurring in the serum. After 15 weeks on high-fat diets, the increase in liver alkaline phosphatase activity was more pronounced in rats receiving vegetable oils and butter than in those given margarine or lard. Heated rapeseed oil and heated butter produced significant increases in alkaline phosphatase activity in the liver.

5871 THE INFLUENCE OF TAUROCHOLATE AND DEHYDROCHOLATE CHOLERESIS ON PLASMA DISAPPEARANCE AND BILIARY EXCRETION OF INDOCYANINE GREEN IN THE RAT. *(E.)* Vonk, R. J.; Veen, H.; Propr, G.; Meijer, D. K. F. (Dept. Pharmacol., Univ. Groningen, Netherlands). *Naunyn Schmiedebergs Arch. Pharmacol.* 282(4):401-410, 1974.

The pharmacokinetics of indocyanine green (ICG; 3.9 μM/kg and 12.9 μM/kg) were investigated in rats given infusion of either saline, taurocholate (106 μM/hr), or dehydrocholate (106 or 268 μM/hr). During the infusion of saline and taurocholate the plasma concentration of ICG decreased in a mono-exponential manner. However, with dehydrocholate the clearance of ICG from plasma showed two phases with different half lives. The half life of the rapid component (2.2 min) was about the same as the one found in the control experiments. After injection of 12.9 μM/kg ICG the biliary excretion of the dye increased by 138% during taurocholate administration, while an equimolar dehydrocholate infusion resulted in a mean increment of 55%. Under these circumstances the bile flow was stimulated by 195% and 297% resp. With the lower dose of ICG (3.9 μM/kg) there was no stimulation of the biliary ICG excretion with taurocholate. At this dose level an infusion of dehydrocholate (106 μM/hr) enhanced the biliary output of ICG by approximately 54%, while administration of 268 μM/hr resulted in a slight but significant decrease of 31%. These observations can be explained by assuming interaction of the bile acids with the hepatic transport of ICG at different sites. The appearance of the second component of the plasma curve during dehydrocholate infusion is possibly related to a diminished hepatic storage capacity for ICG and is not due to an effect on the primary hepatic uptake or biliary output of the dye.

5872 INFLUENCE OF THE BLOOD ETHANOL CONCENTRATION ON THE ACUTE ETHANOL-INDUCED LIVER TRIGLYCERIDE ACCUMULATION IN RATS. *(E.)* Johnson, O. (Univ. Umea, Sweden). *Scand. J. Clin. Lab. Invest.* 33(3):207-213, 1974.

To determine if the acute ethanol-induced increase in the liver triglyceride concentrations in fasted rats is influenced by blood ethanol concentration when ethanol oxidation proceeds at a maximal rate, rats fasted for 24 hr were given ethanol by continuous i.v. infusion to maintain the blood ethanol concentrations at 10 or 45 mM/liter. Control rats were given saline. The rate of ethanol oxidation was similar in the two groups having different blood ethanol concentrations. The incorporation into liver triglycerides of radioactivity from [9,10-^{3}H]oleic acid, injected through an arterial cannula in the aorta, was increased over control values to the same extent in the two ethanol-treated groups. Thus, the ethanol oxidation proceeded at a similar high rate, and a similar increase in the utilization of plasma free fatty acids for synthesis of liver triglycerides, previously proposed as a major mechanism for the development of the acute ethanol-induced fatty liver, occurred at both blood ethanol concentrations. The liver triglyceride concentrations, on the other hand, were increased in rats with 45 mM/liter ethanol in the blood but not in rats with 10 mM/liter ethanol in the blood. This could be attributed, at least in part, to a decrease in the plasma free fatty acid concentration at the low blood ethanol concentration.

5873 SECRETION OF APOLIPOPROTEINS IN VERY LOW DENSITY AND HIGH DENSITY LIPOPROTEINS BY PERFUSED RAT LIVER.

(E.) Noel, S. P.; Rubinstein, D. (Dept. Biochem., McGill Univ., Montreal, Canada). *J. Lipid Res.* 15(4):301-308, 1974.

The incorporation of labeled amino acids into the peptides of very low density lipoproteins (VLDL) and high density lipoproteins (HDL) secreted by perfused rat liver was studied using a Ringer-albumin solution in the perfusate in place of serum to diminish exchange of peptides between VLDL and HDL. The greatest release of protein, greatest incorporation of amino acid, and highest specific activity were found in VLDL. After separation of the delipidated peptides by electrophoresis on polyacrylamide gel, the incorporation into VLDL peptides was 5-10 times as great as into HDL peptides. There was virtually no incorporation into the peptides of low density lipoproteins (LDL). Approximately 25% of the radioactivity incorporated into perfusate VLDL failed to enter the 13% polyacrylamide gel. The remaining radioactivity was distributed primarily among three peptide bands: one, found in the upper portion of the gel, contained 45% of the total, most of the remainder being found in two rapidly migrating bands. These three peptides appear to approximate those of human apo-C in relative electrophoretic mobility. Most of the HDL peptide radioactivity entering the running gel was found in a band that migrates slightly faster than the main VLDL band. A portion of the radioactivity of this major HDL band did not enter the running gel unless β-mercaptoethanol was present. Greater separation of these two bands by polyacrylamide gel electrophoresis for 24 hr confirmed that the major bands in VLDL and in HDL were different. The rapidly moving peptides of HDL were found to contain very little radioactivity. Determination of the intensity of staining of carrier-free perfusate VLDL and HDL peptides produced a pattern similar to the incorporation of labeled amino acids. It is concluded that the rapidly moving peptides, which may contain activators of lipoprotein lipase, are only secreted as part of the VLDL.

5874 EFFECTS OF LONG TERM FEEDING OF CHENODEOXYCHOLIC ACID ON BIOSYNTHESIS AND METABOLISM OF BILE ACIDS IN THE RAT.

(E.) Danielsson, H.; Johansson, G. (Karolinska Inst., Stockholm, Sweden). *Gastroenterology* 67(1):126-134, 1974.

The effects of chenodeoxycholic acid on several hydroxylations in the biosynthesis and metabolism of bile acids, as well as on the composition of biliary bile acid, were studied in male Sprague-Dawley rats fed diets containing 1% chenodeoxycholic acid for up to 2 months. The hydroxylations assayed were those catalyzed by the microsomal fraction of liver homogenate in the presence of reduced nicotinamide adenine dinucleotide phosphates. The 7α-hydroxylation of cholesterol and the 12α-hydroxylation of 7α-hydroxy-4-cholesten-3-one and 5β-cholestane-3α,7α-diol were inhibited by 50% or more after feeding chenodeoxycholic acid for 2 weeks or longer. The 26-hydroxylation of 5β-cholestane-3α,7α-diol was not inhibited. The 6β-hydroxylation of taurochenodeoxycholic acid and lithocholic acid was stimulated by about 50% after 4 weeks of feeding chenodeoxycholic acid. The extent of stimulation was somewhat greater after 8 weeks. The 7α-hydroxylation of taurodeoxycholic acid was stimulated 20-80% by chenodeoxycholic acid. The effects of chenodeoxycholic acid on the various hydroxylations were readily reversible. Thus, the rates of the different hydroxylations in rats fed chenodeoxycholic acid for 3 and 8 weeks and a control diet for 1 week did not differ significantly from those of corresponding controls. Similarly, in rats fed chenodeoxycholic acid for 3 weeks and subjected to bile drainage and starvation for 2 days, the extent of stimulation of 7α-hydroxylation of cholesterol and 12α-hydroxylation of 7α-hydroxy-4-cholesten-3-one was the same as in the controls. The composition of biliary bile acids was determined after 3 weeks of feeding chenodeoxycholic acid. Cholic acid and deoxycholic acid were virtually absent. However, after 1 day of biliary drainage, rats previously fed chenodeoxycholic acid started to synthesize cholic acid.

5875 PYRUVATE CARBOXYLASE IN HUMAN LIVER: APPARENT LOSS OF A COMPONENT OF CATALYTIC ACTIVITY IN A FORM OF LACTIC ACIDOSIS WITH HYPOGLYCEMIA.

(E.) Delvin, E.; Scriver, C. R.; Neal, J. L. (Montreal Shriners Hosp. Crippled Child., Canada). *Biochem. Med.* 10(2):97-106, 1974.

Pyruvate carboxylase activity in human liver was measured by a modification of the method of Utter and Keech. The enzyme is located in mitochondria. Activity in homogenates at a final dilution of 1:100 is directly proportional to time of incubation and amount of tissue incubated. Concentration-dependent kinetics with pyruvate between 0.1 mM and 10 mM, and in the presence of 0.7 mM acetyl-coenzyme A, reveal a low-Km component (Km, 0.3 mM) and a high-Km component (2.4 mM). When the observed total activity is resolved into two discrete components the corrected Km values are 0.4 and

3.7 mM, resp. A neonate with intermittent lactic acidosis, associated with fasting hypoglycemia, and hyperpyruvicacidemia (1 mM *versus* normal value of 0.1 mM) had deficient pyruvate carboxylase activity, with a missing low-Km component. These findings indicate considerable complexity in the catalytic function for pyruvate carboxylation in human liver.

5876 PROSTAGLANDIN E_1 EFFECTS ON ETHANOL METABOLISM IN THE RAT. *(E.)* Lalyre, Y.; Scruggs, W.; Wilson, D. E. (Univ. Illinois Med. Ctr., Chicago). *Prostaglandins* 6(6):489-494, 1974.

The effect of prostaglandin E_1 (0.8 mg/kg s.c.) on the metabolism of a single intragastric dose of alcohol (6 g/kg) given to Sprague-Dawley rats that had been previously maintained on a normal diet or on an alcohol-supplemented diet was studied. Neither acute nor chronic administration of prostaglandin E_1 affected the disappearance of alcohol from blood of animals fed either the control or the alcohol diet. Prostaglandin E_1 did not affect alcohol dehydrogenase activity of either group of animals. These studies suggest that the protective effect of prostaglandin E_1 on alcohol-induced fatty liver in rats is not related to a direct action on alcohol metabolism. In other experiments, animals received diets containing known concentrations of specific fatty acids. Animals fed diets deficient in essential fatty acids, thus preventing prostaglandin synthesis, and fed alcohol without prostaglandin E_1 supplementation were unable to release fatty acids deposited in the liver. This suggests that the major action of prostaglandin E_1 may be on the hepatic release of lipids.

5877 THE EFFECT OF SEX ON CERTAIN PROPERTIES OF THE VERY LOW DENSITY LIPOPROTEIN SECRETED BY THE LIVER. *(E.)* Wilcox, H. G.; Woodside, W. F.; Breen, K. J.; Knapp, H. R.; Heimberg, M. (Vanderbilt Univ. Sch. Med., Nashville, Tenn.). *Biochem. Biophys. Res. Commun.* 58(4):919-926, 1974.

Livers from normal fed male and female Holtzman rats were perfused with a diluted blood-buffer medium containing 0-1773 μM oleic acid in the form of a complex with bovine serum albumin. Over a wide range of free fatty acid concentrations, livers from female rats secreted greater quantities of triglyceride into the perfusate than did livers from male rats. This greater potential of the female to esterify free fatty acids to triglyceride undoubtedly stimulates increased output of VLDL, which is the primary transport form for triglyceride from the liver. The inherently greater capacity of livers from female rats to secrete triglyceride is probably the result of certain hormonally mediated control mechanisms. The hormones which may be responsible probably include gonadal steroids and pituitary gonadotrophins. The very low density lipoprotein (VLDL) carrier for triglyceride secreted by livers from female rats was a larger particle and contained less phospholipid and sterol/mol triglyceride than the VLDL secreted by livers from male rats. Since plasma triglyceride concentrations in female rats are similar to or lower than those in male rats, the greater output of triglyceride VLDL in females suggests that sex-dependent differences in the rates at which VLDL triglyceride is utilized *in vivo* may be related to the lipid composition and physical properties of the VLDL secreted by the liver.

5878 EFFECT OF THEOPHYLLINE ON HEPATIC EXCRETORY FUNCTION. *(E.)* Barnhart, J. L.; Combes, B. (Univ. Texas Southwestern Med. Sch., Dallas). *Am. J. Physiol.* 227(1):194-199, 1974.

Theophylline administered i.v. to anesthetized dogs in an average dose of 17.0 mg/kg resulted in increases in bile flow from the value for control animals of 0.167 ml/min to that for treated animals of 0.240 ml/min and in proportionate increases in biliary clearance of erythritol-^{14}C, but no increase in bile salt excretion. These results confirm earlier findings that theophylline-induced choleresis is canalicular in origin and is independent of bile salt excretion. In addition, the studies demonstrated that theophylline and its metabolites are excreted into bile, but in amounts insufficient to account *via* their osmotic effects for the increase in bile flow. Maximum rates of excretion of sulfobromphthalein sodium (BSP T_m) did not change significantly during theophylline-induced choleresis. This latter observation provided strong evidence that taurocholate-induced enhancement of BSP T_m found in previous studies is related to taurocholate excretion *per se* rather than to increased canalicular bile flow induced by taurocholate excretion.

5879 THE STUDY OF BILE SALT KINETICS IN THE EXPERIMENTAL ANIMAL USING A NEW TECHNIQUE. *(E.)* Deitrick, J. E.; McSherry, C. K.; Thorbjarnarson, B.; Glenn, F. (New York Hosp.-Cornell Med. Ctr., N.Y.). *J. Surg. Res.* 16(5):559-563, 1974.

An animal model which will permit ease of bile sampling in the presence of an intact functioning biliary system for both short- or long-term experiments without reliance upon indwelling catheters has been developed. Six female baboons underwent cholecystopexy, a procedure which secures the fundus of the gallbladder to the right anterior abdominal wall. A right paramedian incision was employed, and a 1.5-cm button of peritoneum excised from the right anterior abdominal wall in the area immediately overlying the fundus of the gallbladder as it projects beyond the liver edge. The fundus of the gallbladder was then sutured to the cut edge of peritoneum to secure it to the anterior abdominal wall. The site of the cholecystopexy was marked by securing a stainless steel wire suture in the anterior rectus fasia of the abdominal wall directly overlying the fundus of the gallbladder. The wire was palpated through the skin and the abdomen then closed in layers. Bile samples were obtained by percutaneous aspiration of the gallbladder with needle and syringe 10 days postoperatively. The data obtained confirm that the gallbladder functions normally following cholecystopexy and suggests that cholic and chenodeoxycholic acids may vary independently in their kinetic activity. It is suggested that this experimental model will be very useful for the study of drug-induced changes in the composition of bile.

5880 ARGINASE ACTIVITY, ARGININE AND ORNITHINE OF PLASMA IN EXPERIMENTAL LIVER DAMAGE. *(E.)* Cacciatore, L.; Antoniello, S.; Valentino, B.; De Ritis, F. (Sch. Med., Univ. Naples, Italy). *Enzyme* 17(5):269-275, 1974.

In the acute phase of CCl_4 poisoning due to i.p. administration of 10% CCl_4 (1.30 ml/100 g) to Sprague-Dawley male rats, a marked increase occurred in plasma arginase activity together with a simultaneous significant increase in ornithine and disappearance of arginine. To confirm the metabolic action of arginase at the plasma level, normal rat plasma containing arginine but almost no arginase and poisoned rat plasma containing arginase (over 4000 IU) without arginine were incubated together at 37 C for 30 min. Following incubation, arginine disappeared completely and ornithine increased significantly. No significant change in urea concentration was noted. The data show that concurrently with effects of CCl_4 on catabolic sequence of the urea cycle in liver cells arginine disappears from the plasma with probable further damage to the ammonia detoxification mechanism. Results also demonstrated that liver arginase which increases during necrotic liver damage still acts at the plasma level to transform arginine into ornithine and urea.

5881 A PHYSIOLOGICAL MODEL TO STUDY GALLBLADDER FUNCTION IN PRIMATES. *(E.)* O'Brien, J. J.; Shaffer, E. A.; Williams, L. F.; Small, D. M.; Lynn, J.; Wittenberg, J. (Boston Univ. Med Ctr., Mass.). *Gastroenterology* 67(1):119-125, 1974.

A primate model employing awake cholecystopexed baboons has been designed to permit quantitative studies of gallbladder function and its influence on the hepatic secretion of bile salts. Duodenal perfusion with ^{3}H-inulin measures total bile salt output into the duodenum, while periodic percutaneous sampling of gallbladder bile labeled with ^{14}C-inulin permits quantitation of changes in volume and bile composition in the gallbladder. The appearance of ^{14}C-inulin in the duodenum quantitates gallbladder emptying. The presence of the catheter does not change the gallbladder's ability to concentrate either radiographic dye or bile salts, nor does it interfere with or induce contraction. During fasting, hepatic bile salt secretion was low (about 5 µM/min) with less than ½ the output entering the gallbladder. No gallbladder contents appeared in the duodenum until contraction was induced by cholecystokinin. However, after gallbladder contraction with mobilization of the bile salt pool, hepatic bile salt secretion increased 2- to 4-fold. The preliminary data suggest that gallbladder filling and emptying play a role in governing the movement of bile salts around the enterohepatic circulation.

5882 ENZYME ACTIVITIES OF THE PERFUSED EX-VIVO PORCINE LIVER: IMPORTANCE OF A PHYSIOLOGICAL PERFUSATE. *(E.)* Baker, P. R.; Cuschieri, A. (Dept. Surg., Univ. Liverpool, England). *Scand. J. Gastroenterol.* 9(1):65-71, 1974.

To determine possible causes for failure of liver preservation by perfusion techniques, the activities of 5 cytoplasmic enzymes (pyruvate kinase, aldolase, glucose-6-phosphate dehydrogenase, sorbitol dehydrogenase, and isocitrate dehydrogenase) were studied in homogenates of *ex-vivo* pig livers perfused by isolated or auxiliary perfusion. In the isolated perfusion system, livers were supplied with diluted blood through a completely artificial circuit with no replenishment of essential constituents. In the other system, livers received blood maintained in a physiological condition by living donor pigs. With auxiliary perfusion livers had normal to high enzyme activities. Activities of all 5 enzymes were lower in the isolated perfused livers, with especially low levels of fructose diphosphate-stimulated pyruvate kinase, sorbitol dehydrogenase, and isocitrate dehydrogenase. The decrease in pyruvate kinase activity was probably due to a deficiency in the L form of this enzyme since activity was abnormally low only with added fructose diphosphate. Because this enzyme plays a key role in glycolysis, its reduced activity may be partly responsible for the observed functional impairment in the isolated perfused liver. These results indicate that the type of perfusion system, and in particular the quality of the perfusate, determines whether enzymes involved in metabolic processes will be present in normal or reduced amounts in hepatic cells. This in turn must influence the extent to which the perfused liver can function in a normal capacity.

5883 SPECTRAL STUDIES ON THE RAPID UPTAKE AND SUBSEQUENT BINDING OF DRUGS TO CYTOCHROME P-450 IN ISOLATED RAT LIVER CELLS. *(E.)* Von Bahr, C.; Vadi, H.; Grundin, R.; Moldeus, P.; Orrenius, S. (Karolinska Inst., Stockholm, Sweden). *Biochem. Biophys. Res. Commun.* 59(1):334-339, 1974.

The rate of formation of type I spectral change, resulting from the formation of a cytochrome P-450-substrate complex, was studied in suspensions of isolated rat liver cells after addition of 5.3 mM of hexo-, amo-, hepta-, and butobarbital. Results obtained with liver hepatocytes were compared with those obtained with liver homogenates and microsomes. This study was primarily designed to determine whether hepatic drug uptake occurs by passive diffusion or involves an energy-consuming process. Complex formation between the drug and cellular cytochrome P-450 was rapid and occurred within a few seconds but was considerably slower than that with homogenates or microsomes. Preincubation of the isolated liver cells with rotenone, which decreases cellular ATP to 5-10%, had little effect on the rate of formation of hexobarbital-produced type I spectral change. The effect of temperature on the rate was moderate ($Q_{10}=1.3$). Studies with the different barbitals showed a relation between the rate of drug-cytochrome complex formation and the lipid solubility of the drug used. It was concluded from these findings that drug uptake into the hepatocytes occurs by a non-energy-requiring diffusion process.

5884 EFFECT OF PHENOBARBITAL ADMINISTRATION ON THE SUBCELLULAR DISTRIBUTION OF VITAMIN D_3-^{3}H IN RAT LIVER. *(E.)* Hahn, T. J.; Scharp, C. R.; Avioli, L. V. (Jewish Hosp. St. Louis, Mo.). *Endocrinology* 94(6):1489-1495, 1974.

The effect of phenobarbital on *in vivo*, hepatic subcellular uptake of vitamin D_3 was studied in 6-week-old male Wistar rats. Phenobarbital (75 mg/kg/day i.p.) was administered for 5 days and on the 6th day 5 U of 1,2-^{3}H-labeled vitamin D_3 in 0.1 ml rachitic rat serum were injected into the jugular veins of treated and control animals. Animals were sacrificed 30 and 90 min after injection, their livers were homogenized and separated into subcellular fractions by centrifugation procedures, and the different fractions were analyzed for protein content and radioactivity. Phenobarbital treatment did not significantly affect total liver uptake of the vitamin, but subcellular distribution of the vitamin was markedly altered. In phenobarbital-treated animals, radioactivity associated with the smooth endoplasmic reticulum was significantly increased and that associated with the mitochondrial fraction significantly decreased after both 30 and 90 min. Increased binding of vitamin D_3 by smooth endoplasmic reticulum in the treated animals correlated well with increased content of smooth endoplasmic reticulum protein. Comparison of smooth endoplasmic reticulum uptake of labeled vitamin D_3 after 30 and 90 min suggests that the rate at which the smooth endoplasmic reticulum metabolizes vitamin D_3 is increased in phenobarbital-treated rats. Chromatography of the radioactivity associated with the various cell fractions showed significantly increased production of polar vitamin D_3 metabolites by the smooth endoplasmic reticulum in the treated animals. The increased conversion to polar products and decreased mitochondrial uptake of vitamin D after phenobarbital treatment may be significant in the pathogenesis of drug-induced osteomalacia.

5885 EFFECTS OF INHIBITORS OF PROTEIN AND RIBONUCLEIC ACID SYNTHESIS ON α-NAPHTHYLISOTHIOCYANATE-INDUCED HYPERBILIRUBINEMIA, SULFOBROMOPHTHALEIN RETENTION AND PROLONGATION OF PENTOBARBITAL HYPNOSIS. *(E.)* Indacochea-Redmond, N.; Witschi, H.; Plaa, G. L. (Fac. Med., Univ. Montreal, Canada). *J. Pharmacol. Exp. Ther.* 189(1):278-284, 1974.

The effects of pretreatment with inhibitors of protein and/or RNA synthesis on hyperbilirubinemia, BSP retention, and prolongation of pentobarbital narcosis induced by α-naphthylisothiocyanate (ANIT, 300 mg/kg p.o.) were studied in Holtzman rats. Actinomycin D, cyclohexamide, and ethionine markedly decreased or inhibited ANIT-induced hyperbilirubinemia even at doses much lower than those commonly used for inhibition or protein and/or RNA synthesis. Minimum inhibitory i.p. doses were 50 µg/kg actinomycin D, 0.05 mg/kg cyclohexamide, and 50 mg/kg ethionine. None of these inhibitors had any effect on BSP retention measured 2 hr after ANIT administration. However, if BSP retention was assessed 24 hr after ANIT, a significant inhibition was produced by pretreatment with 100 µg/kg actinomycin D, 2 mg/kg cyclohexamide, and 400 mg/kg ethionine. When the animals were pretreated (45 mg/kg for males and 30 mg/kg for females i.p.) 1 hr before ANIT, none of the inhibitors studied had an effect on prolongation of pentobarbital sleeping time produced by ANIT. These results suggest that unimpaired protein synthesis may be involved in some of the hepatotoxic effects of ANIT but not in others. The events that lead to hyperbilirubinemia and cholestasis after ANIT are apparently unrelated to those responsible for BSP retention and prolongation of pentobarbital narcosis.

5886 EFFECT OF RENAL DENERVATION AND α-ADRENERGIC BLOCKAGE ON SODIUM EXCRETION IN DOGS WITH CHRONIC LIGATION OF THE COMMON BILE DUCT. *(E.)* Chaimovitz, C.; Massry, S. G.; Friedler, R. M.; Coburn, J. W. (Cedars-Sinai Med. Ctr., Los Angeles, Calif.). *Proc. Soc. Exp. Biol. Med.* 146(3):764-770, 1974.

Chronic ligation of the common bile duct in dogs causes sodium retention and a blunted natriuretic response to extracellular volume expansion. Since increased sympathoadrenal activity plays an important role in other sodium-retaining states, the present study was undertaken to evaluate the role of renal denervation and α-adrenergic blockade on the renal handling of sodium in dogs with chronic ligation of the common bile duct. Renal denervation was accomplished by stripping all visible nerves from the left renal artery of 6 dogs and coating with phenol. Dibenzyline infusion was carried out with the left renal artery in amounts sufficient to deliver 3.6 µg/min in 3 dogs and 15 µg/min in 3 other dogs. Extracellular volume expansion was produced with i.v. infusion of 0.45% NaCl. Six normal dogs were used as controls. Urinary excretion of creatinine, *p*-aminohippurate, and sodium was followed. Neither renal denervation or dibenzyline infusion affected creatinine or *p*-aminohippurate clearance. Both produced a slight but significant increment in urinary sodium excretion, but these changes were not different from those observed after renal denervation in normal animals. Also, these procedures did not improve the response to saline infusion in dogs with chronically ligated common bile ducts. These data indicate that the sympathoadrenal activity does not play an important role in the salt-retaining state that follows chronic ligation of the common bile duct.

5887 INHIBITION OF RELEASE OF HEPATIC TRIGLYCERIDE BY ETHANOL: A REAPPRAISAL. *(E.)* Annable, W.; Cooper, C. (Dept. Biochem., Case Western Reserve Univ., Cleveland, Ohio). *Biochem. Pharmacol.* 23(14):2063-2068, 1974.

Administration of ethanol (2 g/kg i.p.) to male Sprague Dawley rats, starved for 48 hr, increased hepatic triglyceride levels from 4 to 9 mg/g liver within 90 min; levels normalized 24 hr after ethanol injection. Peak levels of plasma ethanol of 200 mg/100 ml were reached within 1 hr, and alcohol was completely absent at 7 hr, with increased levels of hepatic lipids persisting for 24 hr. When Triton WR 1339, used to prevent the action of clearing factor lipase on plasma lipoproteins, was administered (100 mg/g i.v.), serum triglycerides increased linearly from 70 to 260 mg/100 ml within 90 min after injection. However if ethanol was injected 2 hr before Triton, plasma triglyceride levels (40 mg/100 ml at time of Triton administration) rose to only 80 mg/100 ml within 90 min. Over an 8 hr period, this depression of Triton-induced hyperlipidemia persisted until ethanol disappeared from the blood within 7 hr. Except for the lag period, the degree of hyperlipidemia inhibition roughly paralleled changes in plasma ethanol values. It is concluded that ethanol inhibits the movement of triglycerides out of the liver and that this inhibition may be related to the plasma ethanol concentration. The data presented are sufficient to warrant reappraisal of current views regarding ethanol-induced fatty liver.

5888 HORMONE-SENSITIVE ADENYLATE CYCLASE ACTIVITY AS A MARKER TO DISTINGUISH BETWEEN BLOOD SINUSOIDAL AND BILE CANALICULAR SURFACE FRAGMENTS IN RAT LIVER PLASMA-MEMBRANE SUBFRACTIONS. *(E.)* Wisher, M. H.; Evans, W. H. (Natl. Inst. Med. Res., London, England). *Biochem. Soc. Transact.* 2(3):407-408, 1974.

Six cell membrane subfractions from 3 rat livers were prepared: 3 by rate-zonal and density-gradient centrifugation (light, heavy A, and heavy B subfractions) and 3 by flotation in sucrose gradients followed by density-gradient centrifugation (nuclear light, nuclear heavy, and microsomal light subfractions). Electron microscope examination showed a vesicular composition of the 3 light subfractions, while the heavy A and B contained many membrane strips associated with desmosomes and gap junctions; the nuclear heavy subfraction was composed of both vesicles and junctional complexes. Since hormone-sensitive adenylate cyclase activity is theoretically localized at or near the blood sinusoidal surface of hepatocytes, this enzyme was used to determine the origin of subfraction fragments, whether from blood sinusoidal, bile canalicular or intercellular surface. The addition of glucagon to each subfraction increased basal adenylate cyclase activity 3-fold in heavy A and B, 4-fold in nuclear light and heavy, and 9-fold in microsomal light subfractions. No glucagon response occurred in the light subfraction. These results suggest that the microsomal light subfraction, showing highest stimulation by glucagon, contains plasma membrane fragments from the blood sinusoidal surface. The absence of glucagon stimulation in the light fraction indicates its components originate from the bile canalicular surface. Response to glucagon, together with presence of intercellular junctions, showed that the 3 heavy subfractions (nuclear heavy, heavy A, and heavy B) contain fragments derived predominantly from the intercellular and adjacent blood sinusoidal surfaces. The procedures used here are particularly appropriate for the preparation of biochemically characterized fractions, each containing specific plasma membrane fragments from the 3 main surface domains of hepatocyte cell membranes.

5889 STUDIES ON THE APPEARANCE OF A COPPER-BINDING PROTEIN IN RAT LIVER. *(E.)* Bremner, I.; Davies, N. T. (Rowett Res. Inst., Aberdeen, Scotland). *Biochem. Soc. Transact.* 2(3):425-427, 1974.

Male rats were injected i.p. with 100 or 300 μg Cu^{++} (as CuSO$_4$ in physiological saline) to determine whether Cu plays a role in controlling the synthesis or degradation of a Zn- and Cu-containing metallothionein-like fraction in the liver (fraction III). Although large individual variations were observed, hepatic contents of both Cu and Zn increased in rats sacrificed 8 hr. after 100μg Cu^{++} injection. Cu and Zn were found together in fractions I, II, and III separated from liver cytosol by gel filtration on Sephadex G-75. The molecular weights of these fractions were approximately 65,000, 35,000, and 12,000 resp. The combined Cu and Zn content of fraction III was directly related to the hepatic Zn content. Injection of 300μg Cu^{++} produced qualitatively similar effects on hepatic Zn and Cu contents, but variability was greatly decreased. Hepatic Cu contents increased gradually throughout the observation period, while Zn contents began to increase 2 hr after administration of Cu^{++}. Initially, Cu accumulated mainly in fraction I, while the Cu content of fraction III increased progressively with time, the largest increases occurring after a decrease in the Cu content of fraction I and simultaneously with an increase in the heaptic Zn content and the appearance of Zn in fraction III. To determine whether Cu induces fraction III independently of Zn, these experiments were repeated on rats which had been kept on a Zn-deficient diet for 21 days. Although the hepatic Zn content did not increase after administration of Cu^{++}, the Cu content of fraction III increased more rapidly than in rats fed a normal diet. About 50% of the increase in the hepatic Cu content 7.5 hr after administration of Cu^{++} was found in fraction III, suggesting that this component may play some functional role in Cu metabolism. When cycloheximide was injected simultaneously with 300 μg Cu^{++} into Zn-deficient rats at a dose that almost completely inhibited amino acid incorporation into hepatic proteins, the amount of Cu in fraction III was inhibited by about 90% 5 hr after injection, but the increase in the hepatic Cu content was reduced by only 20%. These observations indicate that injection of Cu^{++} promotes the synthesis of a low-molecular weight metal-binding protein by a mechanism requiring active protein synthesis. These results conflict with others reported in the literature for ruminants. This conflict may result from species differences or the fact that the ruminant study was performed on animals in equilibrium with respect to their Zn and Cu status, whereas the present research dealth with dynamic changes following acute Cu^{++} administration.

5890 ISOLATION AND CHARACTERIZATION OF BILIARY METABOLITES OF ESTRIOL IN THE RAT. *(E.)* Nambara, T.; Ishiguro, J.; Kawarada, Y.; Tajima, H. (Pharm. Inst., Tohoku Univ., Japan). *Chem. Pharm. Bull. (Tokyo)* 22(4):889-893, 1974.

5949 BIOGENESIS OF BRUSH BORDER MEMBRANES: ALKALINE PHOSPHATASE AND AMINOPEPTIDASE AND THEIR POSSIBLE PRECURSOR PROTEINS AFTER X-RAY IRRADIATION OF SMALL INTESTINE OF C3H MICE. *(E.)*

Wachsmuth, E. D.; Torhorst, A. (Friedrich Miescher-Inst., Basel, Switzerland). *Beitr. Pathol.* 51(3):234-247, 1974.

The previous findings of putative precursor proteins of the brush border membrane enzymes in the apical cytoplasm of crypt cells of the small intestine, and of proximal convoluted tubules of the kidney, was subjectd to confirmation by experiments in which 1200 r x-ray abdominal irradiation was used to affect protein synthesis. The test animals used were 10-12 week old C3H mice. The enzymes studied were alkaline phosphatase and aminopeptidase. Active forms of the enzymes were analyzed in homogenates and their locations in tissue sections was determined by histochemical methods. The inactive putative precursors were localized by an immuno-histochemical method. An effect of x-ray irradiation could be seen only in the small intestine, not in the kidney. In the early degeneration phase resulting from the irradiation, both the putative precursor proteins and the active enzymes increased. In the late degeneration phase, the putative precursors disappeared first from the crypts of the duodenum and the ileum, followed by the disappearance of the active enzymes from the brush border membranes of the villi. In the regeneration phase, the putative precursors had already reappeared at the time when the active enzymes became detectable in the villi membranes. The appearance of cytoplasmic putative precursors proteins thus appeared to be a prerequisite for the appearance of brush border membrane enzymes. This was consistent with the putative precursors being true precursors of the active enzymes.

5950 SUBCELLULAR LOCALIZATION OF ENTEROKINASE IN HUMAN SMALL INTESTINE. *(E.)*

Schmitz, J.; Preiser, H.; Maestracci, D.; Crane, R. K.; Troesch, V.; Hadorn, B. (Rutgers Med. Sch., Piscataway, N.J.). *Biochim. Biophys. Acta* 343(3):435-439, 1974.

Brush border membrane was isolated from homogenized human intestinal mucosa by centrifugal fractionation and was assayed for enterokinase, using sucrase and alkaline phosphatase as markers. It was found that enterokinase activity in man as in the rat, guinea pig, and pig, occurs in close association with the brush border membrane. However, a second localization may exist since a fraction of the mucosal homogenate containing only small amounts of brush border but large amounts of endoplasmic reticulum, basolateral membranes, and mitochondria contained a disproportionately high amount of enterokinase. The enzyme in this particulate fraction occurred in a not fully active form. The finding of the second localization may explain the fact that enterokinase is unaffected or less decreased than other brush border enzymes in patients with active celiac disease and a flat mucosa.

5951 EXTRACORPOREAL PERFUSION OF EXCISED CANINE SMALL BOWEL SEGMENTS. *(E.)*

Grenier, J. F.; Dauchel, J.; Eloy, M. R. (Munic. Hosp., Strasbourg, France). *Digestion* 10(1):82-94, 1974.

A surgical procedure is described for isolating and artificially perfusing a segment of the dog small bowel with whole blood or a suspension of erythrocytes in a culture medium. Techniques of removal without ischemia and catheterization of the lymphatic vessels are reviewed. Such a preparation may be useful for studies of aspects of small bowel metabolism, particularly the absorptive process and external or internal secretions. The procedure also provides a tool for assessing the electrical and mechanical activities of the intestine and the requirements of its blood flow circulation. Intestinal extracorporeal perfusion makes it possible to collect and measure intestinal secretions, even if produced in small volume, because numerous samples of blood, lymph, and tissue are available for a great number of investigations. Further, effects of various stimuli may be investigated with a minimum of interaction and studies may be performed on segments taken at all the levels of the small bowel. It was suggested that this preparation can be adapted to future transplantation surgery and utilized as a means of storing organs prior to grafting.

5952 DEVELOPMENT AND DISTRIBUTION OF LYSOSOMAL ENZYMES AND DISACCHARIDASES IN HUMAN FETAL INTESTINE. *(E.)*

Antonowicz, I.; Chang, S. K.; Grand, R. J. (Harvard Med. Sch., Boston, Mass.). *Gastroenterology* 67(1):51-58, 1974.

The development and topographic distribution of some lysosomal enzymes (α-glucosidase, β-glucosidase, β-galactosidase, β-glucuronidase, N-acetyl-β-glucosaminidase, arylsulfatase, and acid phosphatase) and 4 disaccharidases (lactase, sucrase, maltase, and palatinase) were studied in human fetuses (10-24 weeks old). The specific activities of these enzymes were compared with those of a premature baby (28 weeks gestation) and a baby born at term (39 weeks), as well as those observed in children (aged 2-11 months). The ranges of specific activities of all enzymes except lactase were comparable to those in older infants, even at the earliest time point studied. The topographies of the disaccharidases and α-glucosidase (lysosomal enzyme, assayed at pH 4.0) were similar: the highest activity was found in the proximal jejunum and levels decreased significantly along the rest of the small intestine. β-Galactosidase, β-glucuronidase, N-acetyl-β-glucosaminidase, and acid phosphatase showed maximum activity in the middle section of the small intestine, while β-glucosidase activity was sustained at a high level through both the proximal and middle small intestine, but fell distally. Arylsulfatase activity was essentially constant along the entire small intestine. This investigation clearly demonstrates the early maturation of the lysosomal enzyme system in the small intestine, and suggests that differentiation of these enzymes may be required for normal cell function in developing intestinal mucosa.

5953 FATTY ACID-BINDING PROTEIN IN SMALL INTESTINE. IDENTIFICATION, ISOLATION, AND EVIDENCE FOR ITS ROLE IN CELLULAR FATTY ACID TRANSPORT.

(E.) Ockner, R. K.; Manning, J. A. (Univ. California Sch. Med., San Francisco). *J. Clin. Invest.* 54(2): 326-338, 1974.

A soluble fatty acid-binding protein, molecular weight about 12,000, present in intestinal mucosa and other tissues that utilize fatty acids (including liver, myocardium, adipose, and kidney) was found to bind long chain fatty acids both *in vivo* and *in vitro*. This protein was isolated from the small intestines of male Sprague-Dawley rats by gel filtration and isoelectric focusing. It showed a reaction of complete immunochemical identity with proteins in the 12,000 molecular weight fatty acid-binding fractions of liver, myocardium, and adipose tissue supernates. However, the presence of immunochemically nonidentical 12,000 molecular weight fatty acid-binding protein in these tissues was not excluded. By quantitative radial immunodiffusion, the supernatant concentration in mucosa from the proximal and middle thirds of the jejuno-ileum significantly exceeded that in the distal third, as well as in the duodenum and liver, expressed as μg/mg soluble protein, μg/g DNA, and μg/g tissue. The fatty acid-binding protein concentration in villi was approximately 3 times greater than the crypts. Small quantities of this protein were present in fractions of washed nuclei-cell membranes, mitochondria, and microsomes. However, the amount of the protein solubilized/mg membrane protein was similar for all particulate fractions, and total membrane-associated fatty acid-binding protein was only about 16% of the supernatant fatty acid-binding protein. Intestinal concentration of this protein was significantly greater in animals maintained on high fat diets than on low fat; saturated and unsaturated fat diets did not differ greatly in this regard. The preponderance of fatty acid-binding protein in villi from the proximal and middle intestine, its ability to bind fatty acids *in vivo* as well as *in vitro*, and its response to changes in dietary fat intake, all support the concept that this protein participates in cellular fatty acid transport during fat absorption. Identical or closely related 12,000 molecular weight proteins may serve similar functions in other tissues.

5954 THE EFFECT OF BICARBONATE AND ACIDIFICATION ON WATER AND ELECTROLYTE ABSORPTION BY THE INTESTINE OF NORMAL AND INFECTED (Hymenolepis diminuta:Cestoda) RATS.

(E.) Podesta, R. B.; Mettrick, D. F. (Dept. Zool., Univ. Toronto, Canada). *Am. J. Dig. Dis.* 19(8):725-735, 1974.

Saline solutions differing in hydrogen ion and bicarbonate concentration were perfused *in vivo* into the jejunum and proximal and distal ileum of both uninfected and parasitized rats (*Hymenolepis diminuta*). In both the parasitized and uninfected animals, the jejunum and proximal ileum were acidified *via* a hydrogen-ion secretory mechanism, as was the infected distal ileum. The intestinal lumen was further acidified in infected rats since *H. diminuta* secretes hydrogen ions. Bicarbonate stimulated absorption of sodium, bicarbonate, and fluid in the uninfected jejunum, in all the regions of the infected intestine, and also by the parasites. This accelerating effect of bicarbonate was pH-sensitive; it is considered of questionable importance in the acidic postprandial proximal intestine. When the pH of the luminal fluid was lowered, intestinal absorption of salt and water diminished, or a net secretion of isotonic fluid occurred. The distal ileum was less sensitive to pH changes. Low luminal pH stimulated water and electrolyte absorption by *H. diminuta*, but absorption was reduced in all 3 regions of the infected small intestine, due either to reduced absorption or enhanced secretion.

5955 HISTOCHEMICAL AND ELECTRON MICROSCOPIC OBSERVATIONS ON THE DEVELOPMENT, NEURAL CONTROL AND FUNCTION OF THE PANETH CELLS OF THE MOUSE.

GENERAL

5958 EFFECT OF VARIOUS PARENTERAL NUTRITIONAL SOLUTIONS ON HEPATIC BLOOD FLOW IN DOGS.

(E.) Hallberg, D.; Soda, M. (Karolinska Inst., Stockholm, Sweden). *Acta Chir. Scand.* 140(3):226-231, 1974.

Different solutions for parenteral nutrition were studied for their effect on hepatic blood in adult mongrel dogs of both sexes. Hepatic blood flow was measured by electromagnetic flow meters on the hepatic artery and the portal vein. Each solution was injected i.v. into a peripheral vein at a constant rate of 0.64-1.14 ml/kg/min for a total volume of 100 ml. No significant effects were observed for blood, Ringer solution, or fat emulsion (20% Intralipid). A significant increase in hepatic blood flow was observed for hypertonic solutions (5.5% glucose, 28%; 10% fructose, 38%; and 15% glucose, 55%). However, amino acid solutions produced the most pronounced rise: Vamin 135%, Intramin 64%, and Aminosol 60%. (Vamin contains 70 g/liter of 18 amino acids; Intramin 66 g/liter of 11 amino acids; and Aminosol 100 g/liter of 18 amino acids but at greater concentrations than Vamin.) The i.v. administration of hypertonic solutions seems to induce vasodilation of the splanchnic vascular bed as well as a decrease in vascular resistance. It is suggested that hyperosmolality could inhibit contractile activity of vascular smooth muscle cells and cause dilation of resistance vessels. Although the infusion rate was high in this study, the fact that the amino acid mixtures showed a more marked increase in pressure and in flow than did other solutions with a comparable osmolality raises the possibility that one or several of the various amino acids have some specific effect on hepatic blood flow. In addition, previous observations that plasma glucagon increases during hyperaminoacidemia suggest a possible hormonal cause of effect on hepatic blood flow. The metabolic physiology of amino acids in giving rise to changes in the blood levels of glucagon and insulin and in influencing the distribution of hepatic blood flow requires further study.

5959 IMMUNE-MEDIATED EMIGRATION OF NEUTROPHILS INTO THE LUMEN OF THE SMALL INTESTINE. *(E.)* Bellamy, J. E. C.; Nielsen, N. O. (Western Coll. Vet. Med., Univ. Saskatchewan, Saskatoon, Canada). *Infect. Immun.* 9(4):615-619, 1974.

Pigs were actively immunized to bovine serum albumin (BSA) by 3 s.c. inoculations of 140 mg BSA. After 4-hr exposure of intestinal mucosa to BSA (525 mg/10-cm ligated loop), immunized animals showed a 20- to 30-fold increase in the numbers of neutrophils entering the intestinal lumen when compared with nonimmune controls. This response was specific for the immunizing antigen and could be transferred to nonimmune animals with immune serum. The emigration of neutrophils through the intestinal mucosa was not accompanied by edema, hemorrhage, and thrombosis which were apparent after intradermal inoculation of BSA into the same animals. The intestinal mucosa showed no evidence of neutrophil emigration or any other abnormal features 24 hr after mucosal exposure to BSA. These observations suggest that emigration of neutrophils into the intestinal lumen can be a specific, antibody-mediated immune response which occurs in the absence of intestinal injury. By determining, in part, neutrophil loss from the body through this mechanism, enteral antigens of all types may be involved in the regulation of neutrophil production. The integrated action of specifically attracted neutrophils acting as phagocytes and specific antibodies acting as opsonins could be a factor in the elimination or control of specific microorganisms or harmful macromolecules in the intestinal lumen. It is also possible that large numbers of neutrophils, attracted by a specific antigen, disintegrate within the intestinal lumen, releasing intracellular enzymes and antibacterial substances that inactivate or destroy the offending antigen.

5960 PREDOMINANT GRAM-POSITIVE BACTERIA IN HUMAN FECES: NUMBERS, VARIETY, AND PERSISTENCE. *(E.)* Gossling, J.; Slack, J. M. (West Virginia Univ. Med. Ctr., Morgantown). *Inject. Immun.* 9(41):719-729, 1974.

The predominant gram-positive bacteria in 47 fecal specimens from 10 healthy men (aged 20-40 yr) were studied by microscopic and cultural counts, by characterization and tentative identification of isolates, and by use of fluorescein isothiocyanate (FITC)-conjugated globulins prepared from some of the isolated bacteria. The number of gram-positive bacteria averaged $10^{10.5}$/g (wet weight) of feces with significant variation from host to host. Characterization of 865 isolates, all strict anaerobes and carbohydrate fermenters, showed 12-39 distinguishable strains from each host and indicated that some strains were present for a period of about 18 months. Of the isolates, 60% belonged to 1 of 5 types, tentatively identified as the following species: *Bifidobacterium adolescentis*, *Eubacterium aerofaciens*, *E. rectale*, *Peptostreptococcus productus*, and *Ruminococcus bromii*. There was a distinct host idiosyncrasy in the pattern of estimated counts of these 5 types. Certain strains resembling *B. adolescentis*, *E. aerofaciens*, and *P. productus*, distinguished with FITC conjugates, were present in their hosts for more than 18 months. In direct smears each strain constituted about 1% of the total bacteria. It is suggested that gram-positive bacteria cannot be considered as a metabolic unit in studying colonic ecology.

5961 REGIONAL CIRCULATORY ADJUSTMENTS TO EATING AND DIGESTION IN CONSCIOUS UNRESTRAINED PRIMATES. *(E.)* Vatner, S. F.; Patrick, T. A.; Higgins, C. B.; Franklin, D. (Harvard Med. Sch., Boston, Mass.). *J. Appl. Physiol.* 36(5):524-529, 1974.

Responses to feeding were investigated in 8 baboons and 1 chimpanzee. Measurements of mesenteric, iliac, renal, and coronary blood flows and arterial pressure were radiotelemetered from the conscious, unrestrained animals continuously at rest during eating, and postprandially until all measurements returned to preprandial control levels. The response to feeding was biphasic. Presentation and ingestion of food by the baboons increased mean arterial pressure (24 mmHg), heart rate (64 beats/min), and mesenteric and renal resistances while coronary and iliac resistances fell. As these effects subsided, a gradual and sustained mesenteric vasodilation occurred. By 50 min postprandially mesenteric flow increased from 212 to a maximum of 372 ml/min, while mesenteric resistance fell from 0.52 to 0.29 mmHg•min/ml. At this time iliac flow decreased by 33 ml/min from 105 ml/min and iliac resistance rose from 0.93 to 1.36 mmHg•min/ml, while arterial pressure, heart rate, renal and coronary flows and resistances were essentially at preprandial control levels. Atropine (0.4 mg/kg. i.m.) attenuated the mesenteric vasodilation postprandially. Postprandial mesenteric vasodilation in the chimpanzee occurred later and was considerably prolonged in duration. This study supports the hypothesis that postprandial angina pectoris is due to an increase in myocardial oxygen demands caused by the elevations in pressure, heart rate, and myocardial contractility that occur with ingestion. Extrapolating these results to patients with diseased coronary vessels, it is suggested that postprandial angina pectoris is due to the inability of diseased coronary vessels to provide added blood flow for the increased metabolic demand on the heart.

5962 ASSESSMENT OF BOWEL VIABILITY USING TECHNETIUM-TAGGED ALBUMIN MICROSPHERES.

(E.) Moossa, A. R.; Skinner, D. B.; Stark, V.; Hoffer, P. (Univ. Chicago Hosp. Clin., Ill.) *J. Surg. Res.* 16(5):466-472, 1974.

Laparotomy was performed in 24 dogs and in 18 rhesus monkeys. In each case, a loop of jejunum (10 dogs and 2 monkeys) or the splenic flexure of the colon (4 dogs and 14 monkeys) was mobilized. The length of small bowel rendered ischemic varied from 6-15 cm while the segment of colon varied from 5-7.5 cm in length. The intramural collateral blood supply was completely interrupted. After ischemic periods varying from about 1/2 to 9 hr, the vascular occlusion was released. Three min later, 1-3 mCi of ^{99M} Technitium-labeled albumin microspheres 15-30 μm in diameter were injected into the upper abdominal aorta *via* the retrograde catheter. Macroscopic assessment of bowel viability proved unreliable in 12 of 18 monkeys and in 15 of 26 dogs. All 18 animals with large-bowel ischemia passed blood and mucus per rectum about 12-48 hr afterward, with the amount of bleeding most pronounced in those animals with marked hyperemic response. Only 5 of the 24 animals with small-bowel ischemia developed frank rectal bleeding. After 3-5 days postoperatively, 13 animals died from bowel perforation and gangrene. All of these had no hyperemic response over the injured segment and both junctional zones. Localized perforation with abcess formation, internal fistula, and partial obstruction occurred in 18 animals. All showed hyperemia over only 1 of the 3 areas. Strictures with varying degrees of large or small bowel obstruction developed in 5 animals. They all had hyperemic response over 2 of the 3 areas. Those 16 animals with normal bowel and minimal adhesions 7-8 weeks postoperatively demonstrated marked hyperemia over all 3 areas. These studies show that (1) rectal bleeding in ischemic colitis occurs mainly during the hyperemic phase; (2) strictures or gangrene can develop as the reactive hyperemia diminishes; and (3) the likelihood of gangrene or stricture developing increases with duration of vascular occlusion. ^{99M} Technitium albumin microspheres may help avoid unnecessary or excessive bowel resection in conditions such as strangulated hernias, mesenteric vascular occlusion, ischemic colitis, and volvulus neonatum.

5963 EFFECTS OF OUABAIN ON INTESTINAL OXYGEN CONSUMPTION.

(E.) Pawlik, W.; Shepherd, A. P.; Mailman, D.; Jacobson, E. D. (Univ. Texas Med. Sch., Houston). *Gastroenterology* 67(1):100-106, 1974.

Most patients with fatal hemorrhagic necrosis of the gut are administered a cardiac glycoside at the onset of their illness. Previously, it was found that the rapid-acting cardiac glycoside, ouabain, constricted intestinal arterioles and reduced mesenteric blood flow. Since tissue necrosis presumes hypoxia as well as ischemia, the effect of ouabain on intestinal oxygen consumption was determined. Two *in situ* canine preparations were used: (1) an isolated loop of gut was autoperfused at constant blood flow, and perfusion pressure was measured across the loop; and (2) a segment of gut with uninterrupted circulation was used, and its blood flow was measured with an electromagnetic blood flow meter. An oxygen difference analyzer continuously measured oxygen content in arterial and venous blood photometrically in both preparations. Ouabain (5 μg/min for 10 min) decreased oxygen consumption and increased mesenteric vascular resistance in the constant-flow preparation, exhibiting a more marked effect on oxygen uptake. The glycoside also reduced oxygen consumption and blood flow in the free-flow preparation. Since a reduced oxygen consumption could result from either decreased capillary perfusion or decreased metabolism, ^{86}Rb clearance which is an index of capillary perfusion, was measured; ^{86}Rb is not metabolized. The clearance of ^{86}Rb was decreased by ouabain. These findings indicate that ouabain not only decreases intestinal blood flow but also decreases intestinal oxygen consumption, probably by constricting precapillary sphincters.

5964 THE ROLE OF THE INTRAMURAL CHOLINERGIC INNERVATION IN THE ACID RESPONSE OF THE PARIETAL CELL TO GASTRIN DERIVATIVES.

(E.) Davison, J. S.; Fahrner, P. C.; Schofield, B.; Tepperman, B. L. (Dept. Physiol., Univ., Dundee, Scotland). *Can. J. Physiol. Pharmacol.* 52(3):469-482, 1974.

The action of nerve-blocking agents on gastric secretion in fundic pouches in dogs was investigated. Histamine (4-12 μg/kg s.c., every 15 min) was used as a direct acid stimulant and was compared with gastrin and derivatives whose action may involve local nerves. In most cases, the inhibitor agent was applied to an established plateau of secretion but in some series, lidocaine (0.083 M) was allowed to act for 1/2 hr before stimulation was commenced. In Heidenhain pouches, atropine (5-20 μg/kg i.v.) produced a mean inhibition of submaximal pentagastrin and gastrin plateaus of -88%. Hexamethonium (1 mg/kg i.v.) was without effect on the pentagastrin response, indicating that only the terminal element of the cholinergic pathway can be involved in gastrin stimulation of the parietal cell. Blockage of this terminal link was demonstrated in Pavlov pouches under insulin stimulation (0.05-1.0 U/kg i.v.), the mean inhibition being -95%. Pepsin secretion was also abolished. Lidocaine was without effect on established histamine plateaus in Heidenhain pouches, and the same result was observed with stimulation by gastrin (0.01 μg/kg/min) and its derivatives. This last result, implying no nervous involvement in the gastrin effect, led to reexamination of insulin experiments where lidocaine was applied before acid secretion. Experiments with lidocaine on established insulin responses gave an inhibition of only -44%. Thus pentagastrin experiments with pretreatment were carried out but the mean inhibition was only -15%, as compared with the mean inhibition of -95% in the lidocaine-pretreatment insulin series. To exclude nonspecific effects of lidocaine, sodium net flux studies were performed. There was a small increase in positive Na$^+$ net flux in the vagal stimulation in which the acid response is virtually abolished. In pentagastrin experiments with lidocaine pretreatment, larger positive net sodium fluxes occurred though acid secretion was not significantly reduced. Therefore, the powerful inhibition in the vagal stimulation experiments is not related to nonspecific effects. It is concluded that the acid secretory response of the parietal cell to gastrin derivatives does not involve excitation of intramural cholinergic nerve elements. However, the response of the parietal cell to gastrin acting directly may be potentiated by acetylcholine release from resting fibers. Until this possibility is excluded, the blocking effects of atropine cannot be regarded as nonspecific.

5965 STUDIES ON THE PASSAGE OF α-CHYMOTRYPSIN ACROSS THE INTESTINE. II. ENZYMIC ACTIVITY AND RADIOACTIVE MACROMOLECULE RECOVERED IN THE MESENTERIC PERFUSATE.

(E.) Moriwaki, C.; Yamaguchi, K.; Moriya, H. (Fac. Pharm. Sci., Sci. Univ. Tokyo, Japan). *Chem. Pharm. Bull.* 22(5):1029-1034, 1974.

Perfusion with Krebs-Ringer solution containing dextran through the mesenteric vascular system was performed on male Wistar rats which had received ^{131}I-labeled α-chymotrypsin in the jejunum. This technique eliminated various blood components, such as the inhibitors of enzymes, which interfere with quantitative assay of small amounts of absorbed enzymes. Under these conditions, non-diffusible ^{131}I-bound substance (s) and N-acetyl-L-tyrosine ethyl ester-hydrolyzing activity were found in mesenteric perfusates. The amount of enzyme absorbed during 90 min was about 0.6% of the infused dose. When mesenteric perfusate was reacted with antiserum against α-chymotrypsin, a precipitin band was formed with perfusate collected during the first 30 min after the administration. These results indicate that a small but significant portion of α-chymotrypsin administered in the intestine can be transmitted into the mesenteric vein without losing its enzymatic and immunochemical properties.

5966 EXTRAVASCULAR CIRCULATION OF ALBUMIN IN EXPERIMENTAL INTESTINAL OBSTRUCTION.

(E.) Herczeg, B. (Semmelweis Med. Univ., Budapest, Hungary). *Z. Exp. Chir. (Jena)* 6(5):337-345, 1973.

To investigate the mechanism of protein loss from the plasma during intestinal obstruction, blood and lymph were analyzed for labeled human albumin before surgery and 5 days after i.v. administration (100 μCi) of ^{131}I-albumin into 7 male and female ileum-ligated dogs. Inhibition of iodine uptake by the thyroid was accomplished through administration of Lugol solution, and the animals were thyroidectomized 6 hr after injection of the labeled albumin. Seven other dogs served as controls. Lymph protein levels were measured as an indirect reflection of protein in the interstitial fluid. Disappearance of labeled albumin from the blood did not differ in the 2 groups. Statistically, the difference between lymph protein levels in ileus and controls was at the borderline of significance in the thoracic duct, but there was decreased protein in the intestinal lymph trunk of obstructed dogs. In ileus, the quantity of transported protein/unit time was decreased; and in both lymphatic trunks, increase in radioactivity was slower and total lymph flow declined compared with controls. In addition, no significant edema was seen in parenchymatous organs, small intestine, or muscles of animals with ileus. These results do not support the theory that increased plasma leakage into the interstitium might explain the great protein loss from the plasma observed during intestinal obstruction.

5967 HEPATIC BLOOD FLOW AND PORTAL VEIN PRESSURE DURING INTRAVENOUS INFUSION OF AMINO ACIDS IN DOGS.

(E.) Hallberg, D.; Soda, M. (Karolinska Inst., Stockholm, Sweden). *Acta Chir. Scand.* 140(3): 232-233, 1974.

The blood flow in the portal vein and the hepatic artery was studied in 10 adult mongrel dogs of both sexes during constant i.v. infusion of different doses (0.1-1.2 ml/kg/min) of an amino acid mixture (Vamin) containing 10% fructose. Systemic arterial and portal vein blood pressures were also recorded. No effect on systemic pressure was observed, but the portal pressure increased significantly even at the lowest studied dose of 0.1 ml/kg/min. At the highest dose, the portal pressure had increased 100%. Hepatic artery and portal vein blood flow also rose, even at small doses, but the increases were significantly more pronounced in the portal vein (e.g., 100% with highest dose) than in the hepatic artery. Results indicate a significant dose-response relation between the rate of solution infusion and both hepatic blood flow and portal blood pressure. Although the doses given were usually pharmacologically high, rates up to 0.2 ml/kg/min may have some clinical applications. Since previous studies showed that amino acid mixtures without fructose influenced portal pressure and flow more than 10% fructose alone, it is possible that the main findings in this study are related to the effect of the amino acids on the splanchnic blood vessels. The effect may be a vasodilation of the capillaries in the intestinal mucosa, similar to that observed after an oral meal of proteins.

5968 EFFECT OF OXYGEN BREATHING ON JEJUNAL TISSUE GAS TENSIONS DURING SUPERIOR MESENTERIC ARTERIAL OCCLUSION.

(E.) Inberg, M. V.; Havia, T.; Arola, M. K.; Niinikoski, J. (Dept. Surg., Univ. Turku, Finland). *Scand. J. Gastroenterol.* 9(4):337-342, 1974.

The effects of superior mesenteric arterial occlusion on jejunal tissue gas tensions in dogs ventilated continuously with air or 100% oxygen were measured by means of an implanted Silastic tube. One dog was used primarily to test the method. The remaining 6 dogs were handled in pairs so that jejunal tissue gas tensions were obtained simultaneously from air-breathing and oxygen-breathing animals. Ventilation of each pair of animals with pure oxygen significantly increased the supply of oxygen in the jejunal wall during superior mesenteric arterial occlusion. It is suggested that this is due to marked collateral circulation of the bowel. During superior mesenteric arterial occlusion the jejunal tissue pCO_2 was consistently higher in oxygen-breathing dogs than in air breathing dogs. This indicates that during the ischemic period the ability of jejunal tissue to produce carbon dioxide is better preserved in animals breathing oxygen. These results tend to support earlier observations that oxygen therapy delays the effects of superior mesenteric arterial occlusion on the intestine.

5969 BLOOD FLOW DURING OBSTRUCTION TO THE VENOUS EFFECT OF PORTACAVAL TRANSPOSITION ON HEPATIC OUTFLOW FROM THE CANINE LIVER.

(E.) Baker, P. R.; Shields, R. (Dept. Surg., Univ. Liverpool, England). *Ann. Surg.* 180(1):89-94, 1974.

A useful model of advanced hepatic lesion for the assessment of portacaval transposition is described, with measurement of hepatic blood flow in dogs having different degrees of outflow block in the liver after such transposition. Complete block of hepatic venous outflow in 5 dogs with portacaval transposition resulted in a steady decline of estimated hepatic blood flow. Four weeks later, mean flow was only 46% of the value obtained 3 days after surgery; however, such reduced flow did not prevent the development of ascites which occurs in dogs with complete hepatic venous outflow block alone. In the longest surviving dog, complete reversal of portal flow was present. When portacaval transposition was performed in 5 dogs with established partial outflow block, estimated hepatic blood flow remained at preoperative levels whether portal hypertension was present or not prior to the second operation. This maintenance of hepatic blood flow was due to continuing venous flow into the portal bed. In a 3rd group of 19 animals with complete hepatic venous outflow block only, the early death of dogs and the development of gastroduodenal ulcers was unexpected since there were no obvious causes of death although the degree of liver damage was extensive when assessed histologically and biochemically. In general, the results indicate that portacaval transposition would probably be of little benefit in cases of advanced cirrhosis since the potential advantage of this procedure, the maintenance of venous inflow to the liver, is not realized. Where the hemodynamic derangement of the liver is less severe, portacaval transposition may be preferable to portacaval shunt in some cases.

5970 PATHOPHYSIOLOGY OF SALMONELLA DIARRHEA IN THE RHESUS MONKEY: INTESTINAL TRANSPORT, MORPHOLOGICAL AND BACTERIOLOGICAL STUDIES.

(E.) Rout, W. R.; Formal, S. B.; Dammin, G. J.; Giannella, R. A. (Walter Reed Army Inst. Res., Washington, D.C.). *Gastroenterology* 67(1):59-70, 1974.

In vivo jejunal, ileal, and colonic water and electrolyte transport were studied in *Salmonella typhimurium*-infected male rhesus (*Macacca mulatta*) monkeys, and alterations in transport were correlated with changes in intestinal morphology and with intraluminal *Salmonella* concentrations. In controls, net water absorption was seen in the jejunum, ileum, and colon. All *Salmonella*-infected monkeys with diarrhea had severe colitis associated with either a marked inhibition of colonic water absorption or net colonic secretion. Monkeys with mild diarrhea had mildly impaired ileal and markedly impaired jejunal transport; in contrast, monkeys with severe watery diarrhea demonstrated net secretion in the jejunum, ileum, and colon. Sodium and chloride transport paralleled water transport in magnitude and direction. In the ileum, the severity of morphological damage and the intraluminal *Salmonella* concentrations correlated with the degree of transport abnormalities and with the severity of the observed diarrhea. However, despite a transport defect in the jejunum, bacterial invasion was never seen and morphological changes were minimal, as were intraluminal *Salmonella* concentrations. These observations suggest that in *Salmonella*-infected monkeys, mild diarrhea may result from the inability of the colon to reabsorb the fluid load presented to it by the small intestine, but severe diarrhea may result from profound transport abnormalities in both the jejunum and ileum superimposed on those in the colon. Unlike enterotoxin-mediated diarrheas, *Salmonella* diarrhea seems to involve both the small and large intestine, and is regularly accompanied by both ileitis and colitis. Whether the abnormalities observed in this study are also similar to those occurring in man is not known and must await human perfusion studies.

5971 THE INFLUENCE OF VENOUS PRESSURE ON FILTRATION FORCES IN THE INTESTINE.

(E.) Johnson, P. C.; Richardson, D. R. (Univ. Arizona Coll. Med., Tucson). *Microvasc. Res.* 7(3):296-306, 1974.

The effect of venous pressure on capillary and tissue hydrostatic and oncotic (colloid osmotic) pressures was studied in the dog intestine. Tissue hydrostatic pressure was measured beneath the serosal surface of the intestine with a fine needle which was inserted while viewing the area under a dissecting microscope. The needle pressure remained essentially at zero when venous pressure was elevated in a stepwise fashion from 0 to 20 mm Hg. In another experiment, the protein concentration of intestinal lymph was measured and used to calculate the lymph oncotic pressure. When venous pressure was elevated from 0 to 25 mm Hg, lymph protein levels fell from 5.1% to 0.8%. Plasma protein levels remained at approximately 6.2% during the experiment. The fall in lymph oncotic pressure with increasing venous pressure was quantitatively identical to the rise in capillary pressure. If it is assumed that lymph oncotic pressure variations quantitatively reflect changes occurring in the interstitium, these results indicate that adjustments in tissue fluid oncotic pressure are important in limiting blood-tissue fluid exchange. The changes in tissue oncotic pressure offer an explanation for the fact that the intestine becomes isogravimetric over a sizable range of venous pressures.

DIAGNOSTIC PROCEDURES

5989 ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY: METHOD OF CHOICE FOR DIAGNOSING CYSTS OF THE COMMON BILE DUCT. *(Ger.)* Nuesch, H. J.; Hahnloser, P.; Fumagalli, I.; Jenny, S.; Deyhle, P. (Cantonal Hosp., Zurich, Switzerland). *Dtsch. Med. Wochenschr.* 98(44):2069-2070, 1973.

Case reports are presented for 2 patients with choledochal cysts which were diagnosed preoperatively by endoscopic retrograde cholangiography. A 41-yr-old woman with a long history of fat intolerance developed symptoms of acute cholecystitis. An i.v. cholangiogram revealed a clover-leaf-shaped cavity in the descending biliary tract which could not be interpreted. Retrograde endoscopic cholangiography demonstrated a pear-shaped proximal dilation of the common bile duct. The cystic and hepatic ducts were also dilated, but the pancreatic duct and intrahepatic bile ducts were of normal size. Two stones were visualized in the gallbladder. The diagnosis of a choledochal cyst was confirmed at surgery, and the gallbladder did not contain 2 stones. A 41-yr-old woman who had undergone cholecystectomy for cholecystolithiasis and recurrent biliary colic 18 yr before developed pancreatitis. A cholecystogram showed marked dilation of the bile ducts, but the patient refused surgery. Endoscopic retrograde cholangiography, performed 2 yr later, showed a massively dilated common bile duct which contrasted with intrahepatic bile ducts of normal caliber; the pancreatic duct was normal. A diagnosis of a choledochal cyst was established and confirmed at surgery. In addition, a stone was found which was not visualized by retrograde cholangiography. Endoscopic retrograde cholangiography is recommended for preoperative diagnosis of choledochal cysts since they are difficult to diagnose from the history, clinical symptoms, and conventional radiological methods. Because any amount of contrast medium can be injected in the biliary tract, this technique can even demonstrate large cysts.

5990 A COMPARISON OF THE BROMSULPHTHALEIN AND GALACTOSE ELIMINATION TEST IN PATIENTS WITH EITHER CHRONIC BOWEL INFLAMMATION OR ALCOHOLIC LIVER DISEASE. *(E.)* Nilsson, L. H.; Hultman, E. (St. Erik's Hosp., Stockholm, Sweden). *Scand. J. Gastroenterol.* 9(3):319-323, 1974.

Simultaneously i.v. infused BSP (5 mg/kg) and galactose (350 mg/kg) were used as a test of liver function in 2 groups of patients over a period of 2 yr. One group consisted of 89 patients (37 men and 52 women, mean age 31 yr) hospitalized for chronic inflammatory bowel disease. The other group comprised 88 patients (78 men and 10 women, mean age 55 yr) with clinical signs of liver damage due to chronic alcohol abuse. In paitients with alcoholic cirrhosis, both substances showed a decreased elimination from the blood. Patients in the alcohol abuse group, with histologically verified steatosis of the liver but without reactive changes in the portal fields, were characterized by a prolonged galactose elimination time but a normal retention of BSP. A normal galactose elimination capacity was typical for the patients with chronic inflammatory bowel disease, whereas the BSP retention was increased in 47% of patients admitted to hospital. The data suggest that the excretory function of the liver is frequently disturbed in chronic inflammatory bowel disease, whereas the parenchymal metabolic function is preserved. This is in accordance with the most common type of liver damage in cases of ulcerative colitis or Crohn's disease.

5991 CORRELATION OF LIVER AND SPLEEN SIZE. DETERMINATIONS BY NUCLEAR MEDICINE STUDIES AND PHYSICAL EXAMINATION. *(E.)* Halpern, S.; Coel, M.; Ashburn, W.; Alazraki, N.; Littenberg, R.; Hurwitz, S.; Green, J. (Univ. California Sch. Med., La Jolla). *Arch. Intern. Med.* 134(1):123-124, 1974.

Since accurate knowledge of the liver and spleen size is often important in diagnosis, scintiphotography of these 2 organs was performed on 214 patients, and the results were correlated with those obtained by physical examination: palpation, percussion, patient positioning, and ballottement. In 113 (53%) patients, the liver was considered to be either enlarged or reduced in size by physical examination compared to 94 (44%) as determined by scintiphotography. Thus, there were 19 false-positive interpretations of liver size by physical methods. In only 29 (14%) patients was the spleen considered to be enlarged by physical examination whereas splenic enlargement was indicated in 92 (43%) patients by scintiphotography, a total of 63 false-negative interpretations by physical methods. Review of the patients' clinical charts showed a concurrence with scintiphotography findings in 141 (66%) patients as to liver size; clinical methods showed 148 (69%) patients with splenomegaly but scintiphotography revealed only 92 cases. However, of these 92, only 26 (28%) splenomegalies were recognized by physical examination. Although scintiphotography is not completely free of subjective interpretation (i.e., determining the size of a 3-dimensional organ by measuring any 2 dimensions), the liver and spleen scintiphotogram offer a relatively clear-cut assessment of the size of these organs, except in the truly borderline cases.

5992 SIMULTANEOUS ESOPHAGEAL AND BRONCHIAL ENDOSCOPY IN 1000 CASES OF ESOPHAGEAL CANCER. *(Fr.)* Chavy, A.; Liguory, C.; de Peyer, R.; Meduri, B.; Fauvet, J.; Lemoine, J. M. (Gustave Roussy Inst. Villejuif, France). *Ann. Gastroenterol. Hepatol. (Paris)* 9(4):319-326, 1973.

In a 12.5-yr. period, simultaneous endoscopic examinations of the esophagus and bronchi were performed on 1000 patients with esophageal cancer. Of these patients, 856 (85.6%) had epidermoid carcinomas and 144 (14.4%) had adenocarcinomas in the lower 1/4 of the esophagus. Histological confirmation of the diagnosis was made at endoscopy in 90.6% of these patients and at surgery or autopsy in the remaining 9.4%. Endoscopy was performed under local anesthesia and was generally well tolerated. Traumatic lesions of the esophagus occurred in only 8 cases (0.8%), and no bronchial complications developed. Tracheal or bronchial anomalies were present in 484 cases (48.4%). These consisted of extrinsic compression in 353 cases

(35.3%), infiltration in 68 (6.8%), and growths in 63 cases (6.3%). All of these anomalies occurred at a level in the bronchial tree corresponding to that of the esophageal tumor. Tracheobronchial lesions most often involved the posterior trachea or the principal left bronchus. The incidence of these anomalies was highest (65%) for tumors in the cervical esophagus, decreasing to 12% for tumors in the lower 1/4 of the esophagus. The finding of tracheobronchial lesions is not only a contraindication for surgical removal of the esophageal tumor, but also a contraindication for high-energy radiotherapy since irradiation of an esophageal tumor which has invaded the bronchial tree increases the risk of fistula formation.

5993 DIBROMSULPHALEIN (DBSP) ESTIMATION OF HEPATIC TRANSPORT FUNCTION IN MAN.

(E.) Dhumeaux, D.; Berthelot, P.; Javitt, N. B. (Henri Mondor Hosp., Creteil, France). *Eur. J. Clin. Invest.* 4(3):181-185, 1974.

BSP and disulfobromophthalein (di-BSP) were given separately in equimolar amounts by i.v. injection or infusion to 15 healthy individuals and 33 individuals with hepatobiliary disease. The patients included subjects with alcoholic cirrhosis (9), viral hepatitis (9), cholestasis due to extrahepatic obstruction (4), and Dubin-Johnson syndrome (2). The slope of the plasma disappearance rate, the relative storage capacity, and the maximum biliary excretion rate for both BSP and di-BSP were calculated. In the normal group the slope of the plasma disappearance rate, 0.234, was significantly greater than for BSP, 0.151, indicating a more rapid plasma disappearance for di-BSP. Similarly the relative storage capacity was significantly higher for di-BSP, 124.6 μmol/μmol/100 ml, than for BSP, 67.7. However, the maximum biliary excretion rate for di-BSP, 10.9 μmol/min, was not significantly different from that for BSP, 9.5. In the cirrhotic patients, there was reduction in these three parameters which was of the same order of magnitude for both dyes, indicating that di-BSP is as sensitive as BSP in the detection of liver disease. Since di-BSP is not conjugated *in vivo*, this suggests that the modifications of BSP disposition in cirrhosis are attributable primarily to a defect in the transport function of the liver cell. Defective conjugation of BSP therefore probably does not contribute significantly to the BSP abnormalities observed in cirrhotic patients. During prolonged infusion of BSP, especially in hepatobiliary disease patients, a large amount of BSP in plasma is actually conjugated. The presence of BSP conjugates in the plasma could theoretically contribute to reduce the BSP storage in these patients. Thus di-BSP, while distributed as a single compound, could provide a more accurate estimate of the relative storage capacity.

5994 RESULTS OF ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY IN DIAGNOSING SYMPTOMS DEVELOPING AFTER BILLARY SURGERY.

(Ger.) Safrany, L.; Barna, L.; Papp, J.; Tari, J. (1st Med. Clin., Semmelweis Univ., Budapest, Hungary). *Z. Gesamte Inn. Med.* 29(10):397-401, 1974.

In a 2-yr period, 238 endoscopic regrograde cholangiographies were performed using the Olympus JF-B duodenoscope and 60% Urographin (meglumine diatrizoate) as the contrast medium. Of these procedures, 148 (62%) were performed on patients who had undergone biliary surgery. Cholecystectomy was the most commonly performed operation, but 42 patients had undergone corrective surgery of various types, particularly enterobiliary anastomoses. Since these anastomoses are sometimes difficult to locate with an endoscope, indocyanine green was injected i.v. Diagnoses consisted of the following: normal biliary tract (36 cases), intrahepatic cholestasis (9), primary biliary cirrhosis (16), sclerosis of the sphincter of Oddi (14), stricture of the common bile duct (19), primary sclerosing cholangitis (2), cholecystolithiasis (2), choledocholithiasis (61), biliary carcinoma (13), carcinoma of the head of the pancreas (17), normal enterobiliary anastomosis (18), pathological changes in an enterobiliary anastomosis, (8), carcinoma of the papilla of Vater (3), and juxtapapillary diverticulum (13). The most common diagnoses in patients with recurrent biliary diseases were choledocholithiasis (33%), stricture of the common bile duct (12%), and hypertrophy of the sphincter of Oddi (8%). In juxtapapillary diverticulum, remnants of food which were present in the papilla produced ascending cholangitis, and dislocation and compression of the papilla or distal common bile duct resulted in cholestasis. Jaundice could develop either as a result of biliary obstruction or of secondary stone formation. In 1 patient recurrent stones were removed from the biliary tract 4 times since the diverticulum had not been diagnosed despite repeated surgery. Endoscopic retrograde cholangiography revealed well-defined organic changes in patients who had been referred with a diagnosis of cystic stump syndrome. It is doubtful that the cystic stump plays any pathogenetic role in postcholoecystectomy syndrome.

5995 THE DIAGNOSIS OF EARLY GASTRIC CANCER.

(E.) Elewaut, A.; Cardon, M.; Mortier, G.; Barbier, F. (Univ. Hosp., Ghent, Belgium). *Tijdschr. Gastroenterol.* 16(2):111-116, 1974.

A review was made of 1445 gastroscopic examinations performed during the period 1968-1971. For most examinations a gastrofiberscope with biopsy was used. A few examinations were performed with a fiber esophagoscope. Out of 154 cases of gastric carcinoma detected or confirmed by endoscopy, 7 cases of early carcinoma (0.48% of all examinations) were proven by histologic examination of the resected stomach. In only 2 cases was malignancy strongly suspected on radiological evidence. This is in contrast to the findings of Japanese authors who succeeded in diagnosing 80% of all cases radiologically using double contrast methods. In 3 of 6 biopsied cases, the diagnosis of carcinoma was confirmed by histologic examination. The 50% failure in obtaining the correct diagnosis by biopsy may be accounted for by the fact that only 2 biopsies were taken in each patient. Suspicion of malignancy was made in endoscopy alone in 5 cases with irregular dark red surface with little nodules, whitish coat, and alteration of the mucosal folds.

which suddenly break off serving as important signs. Early diagnosis of gastric carcinoma is essential since long-term survival depends on early surgery. It is stressed that endoscopic examination be made of every patient with persistent atypical epigastric complaints. Multiple biopsies must be taken at the margin and the base of the ulcer. It is noted that even a healed ulcer may be malignant.

5996 THE SIGNIFICANCE OF THE LIVER-SPLEEN UPTAKE RATIO IN LIVER SCANNING. *(E.)* Wilson, G. A.; Keyes, J.W. (Univ. Michigan Med. Ctr., Ann Arbor). *J. Nucl. Med.* 15(7):593-597, 1974.

In this study of rectilinear liver and spleen scans (posterior view with both organs visible) taken over a 3-yr period on 563 patients (1-88 yr), the relative uptake of ^{99m}technetium sulfur colloid was evaluated by a simple criterion. The method, involving categorization of the scans into groups showing equal or relatively greater uptake by spleen or liver, provided a useful diagnostic criterion with some differential diagnostic significance. Increased splenic uptake was seen in 290 patients (122 males and 168 females, average age 50.5 yr) and most commonly occurred in malignancy (48%), liver cirrhosis (13.4%), and diabetes mellitus (10.7%). No association with anemia was found. Increased uptake by the liver was seen in 58 patients (24 males and 34 females, average age 51.7 yr) and occurred most commonly in malignancies (59%), gastrointestinal disease other than liver (8.6%), and diabetes mellitus (7.0%). Equal uptake by liver and spleen was found in 215 patients (130 males and 85 females, average age 53 yr) and involved malignancy (51.2%), infection (8.4%), and collagen disease and arthritis (6.1%). In general, the presence of an unequal liver/spleen ratio of uptake suggested a chronic rather than an acute process.

5997 CLEARER ROENTGENOGRAPHIC VISUALIZATION OF THE COLON. A STUDY OF A CONVENIENTLY PACKAGED KIT FOR PREPARING THE COLON, AND ITS EFFECT ON ELECTROLYTE BALANCE. *(E.)* Irwin, G. A. L.; Shields, J. E.; Wolff, W. (Nassau County Med. Ctr., East Meadow, N. Y.). *Gastroenterology* 67(1):47-50, 1974.

The results of an investigator-blind controlled evaluation of coded films indicate that a newly available commercial kit is more effective in preparing patients for barium enema roentgenographic visualization of the colon than the standard castor oil and enema procedure. Of the 325 patients studied over an 8-month period, 245 (105 men and 140 women, mean age 57.2 yr) were treated with castor oil and 80 (34 men and 46 women, mean age 55.6 yr) were prepared by kit treatment consisting of a bowel evacuant of magnesium citrates, citric acid, and sodium citrate, followed by phenolphthalein tablets, and potassium bitartrate and sodium bicarbonate enemas. Kit patients also received large quantities of fluids. The kit preparation resulted in considerably improved barium enema studies, was more readily accepted by the patient and nursing staff, resulted in a smaller percentage of repeat examinations, and had no adverse effect on serum electrolytes (sodium, chloride, potassium, carbon dioxide, blood urea nitrogen, and glucose). Repeat studies were ordered in 55.5% of the castor oil group compared with 40% of kit-prepared patients, a statistically significant difference.

5998 RADIOLOGICAL FINDINGS IN RETROGRADE PANCREATOGRAPHY AND THEIR PATHOLOGIC ANATOMICAL SUBSTRATE. *(Ger.)* Nette, L.; Deyhle, X. (Central Inst. Radiol. Diagnosis, Zurich, Switzerland). *Radiol. Clin. Biol.* 43(4):328-333, 1974.

Radiological findings from retrograde pancreatography with Urografin are compared with autopsy findings in 4 patients with pancreatic disease. Radiography revealed duplication of the pancreatic duct with sharp but irregular contours in an alcoholic patient with no clinical evidence of pancreatic disease. Histological examination showed pancreatic fibrosis in which the lobules were constricted by connective tissue. Lipomatosis and pancreatitis with parenchymal necrosis were diagnosed at autopsy in a patient with no clinical or radiological evidence of pancreatitis. In a patient with a carcinoma of the papilla of Vater, radiological examination showed dilatation of the pancreatic duct and its lateral branches with obstruction of the common bile duct in addition to a small papillary tumor. Another patient with extensive metastases from a bronchial carcinoma had histological evidence of acute hemorrahagic necrotizing pancreatitis. In addition to a blurred pancreatic duct with irregular contours, retrograde pancreatography revealed spots of contrast medium emerging at sites where parenchymal necrosis was evident on gross examination.

5999 HUMAN LIVER MITOCHONDRIA. III. ATPase ACTIVITY AS AN INDEX OF MITOCHONDRIAL DAMAGE. *(E.)* Benga, G.; Muresan, L. (Med. Pharm. Inst. Cluj, Rumania). *Biochem. Med.* 10(2):131-145, 1974.

Liver mitochondria from patients with fatty liver, chronic hepatitis, cirrhosis, and obstructive jaundice and from normal subjects were analyzed for ATPase activity. $MgCl_2$ (5 mM), 2,6-diiodo-4-nitrophenol (DNP, 0.05-0.4 mM), and bovine serum albumin (1% final concentration) were added to reaction mixtures containing 5 mM ATP, 150 mM sucrose, 50-75 mM KCl, 50 mM Tris-HCl (pH 8.5), 0.5 mM edetic acid, and 0.1-0.2 mg mitochondrial protein. ATPase in normal mitochondria had a low basal activity, was slightly stimulated by Mg, and was greatly stimulated by DNP. The optimal DNP concentration for maximal stimulation varied with pH and was dependent on the presence of albumin in the incubation mixture. Basal and Mg-stimulated ATPase activity was low at neutral pH and increased at lower and higher pH values; DNP-ATPase activities were low at acid pH and showed a broad maximum in the alkaline pH range. In general, the shape of the pH curves depended on mitochondrial integrity. After aging (1 hr at 37 C), the curves showed a gradual disappearance of DNP-activated ATPase. In 1 patient with fatty liver and reversible mitochondrial damage, Mg-stimulated activity was greater than DNP-stimulated ATPase without albumin; in the presence of albumin, there was a reversal of the ratio DNP-ATPase/Mg-ATPase. In pathological conditions (liver and biliary diseases), irreversible damage occurred. This was characterized by high basal and Mg-ATPase values and little DNP stimulation even in the presence of albumin.

6000 SPECIFIC IMMUNODIAGNOSIS OF HEPATOCELLULAR CARCINOMA BY LEUCOCYTE ADHERENCE INHIBITION. *(E.)* Halliday, W. J.; Halliday, J. W.; Campbell, C. B.; Maluish, A. E.; Powell, L. W. (Dept. Microbiol., Univ. Queensland, Brisbane, Australia). *Br. Med. J.* 2(5915):349-352, 1974.

The leukocyte adherence inhibition test is simple to perform and requires no complex equipment or cultivation or labeling of tumor cells. This technique was used to study 7 cases of primary hepatic tumors, of whom 6 had hepatocellular carcinoma and 1 had hepatoblastoma; 3 cases of secondary hepatic tumors, 1 each of malignant melanoma, adenocarcinoma of the lung, and squamous cell carcinoma of the cervix uteri; 43 cases with other diseases of the liver of whom 33 were cirrhotic (9 alcoholic, 8 with chronic active hepatitis and 16 with hemochromatosis); and 4 with melanoma and adenocarcinomas of the breast, colon, and stomach. The test is based on the observation that when blood leukocytes from a cancer patient are mixed with the corresponding specific tumor antigen, the tendency of the leukocytes to adhere to glass is inhibited. Serum from such patients interferes with this inhibition. This technique gave consistently positive results in confirmed malignant hepatomas and enabled this malignancy to be distinguished from secondary hepatic tumors, nonmalignant liver disease, and other tumors not associated with the liver. Thus, leukocyte adherence inhibition provides a rapid, sensitive and specific test of value in diagnosis. In 2 patients, a positive result preceded the clinical appearance of hepatoma by 2 and 3 years, resp. In a further 4 patients with primary idiopathic hemochromatosis, blocking factor has been detected in the serum but as yet there is no other clinical or laboratory evidence of malignancy. It is suggested that cell-mediated immunity and serum blocking may be the earliest manifestations of malignant hepatoma in these patients.

6001 INTRAOPERATIVE DIAGNOSIS OF TUMOR-LIKE CHANGES IN THE HEAD OF THE PANCREAS BY FINE-NEEDLE ASPIRATION BIOPSY. *(Ger.)* Lederer, B.; Bodner, E. (Pathol. Inst., Univ. Innsbruck, Austria). *Dtsch. Med. Wochenschr.* 99(19):993-996, 1974.

Using a needle 5-8 cm long which has an external diameter of 0.6-0.8 mm, material was aspirated during surgery from the head of the pancreas of 54 patients (37 men and 17 women, aged 34-78 yr; mean age 60 yr). Up to 6 samples were taken from the area to be studied, and material was stained by a modification of the Papanicolau method. Of these 54 patients 33 had malignant tumors of the head of the pancreas, as confirmed by histological examination. No evidence of malignancy was found during follow-up examinations made 8 months or more after surgery in 21 patients with benign changes in the head of the pancreas. Fine-needle biopsy gave a correct diagnosis in 88% of these patients, and no false-positive results were obtained. In 2 cases a diagnosis could not be established because only blood and detritus were aspirated. Fine-needle biopsies appear to be best suited for the diagnosis of carcinomas of the head of the pancreas and distal common bile duct, but failed to diagnose 1 papillary carcinoma. Because of the difficulty of obtaining sufficient material, fine-needle biopsy was less useful in diagnosing metastases in the head of the pancreas. However, metastases from a fibrosarcoma and a small-cell bronchial carcinoma were correctly diagnosed with this technique. Cytological preparations show atypical nuclear changes more clearly than frozen sections obtained during surgery. While it is easy to make an accurate diagnosis of polymorphic adenocarcinomas and undifferentiated carcinomas with fine-needle biopsies some difficulty may be encountered in the differentiated carcinomas.

6002 SERUM α-FETOPROTEIN: DIAGNOSTIC SIGNIFICANCE IN LIVER DISEASE. *(E.)* Ruoslahti, E.; Salaspuro, M.; Pihko, H.; Andersson, L.; Seppala, M. (Dept. Serol. Bacteriol., Univ. Helsinki, Finland). *Br. Med. J.* 2(5918):527-529, 1974.

Raised serum α-fetoprotein levels (>25 ng/ml) measured by radioimmunoassay were found in 19 of 24 (79%) patients with primary liver cancer and in 32 of 311 (10%) patients with other liver diseases. The rise was transient in cases of hepatitis and a transient rise was also seen after alcohol intake ceased in 2 patients with cirrhosis. α-Fetoprotein levels exceeding 500 ng/ml were 30-50 times more common in primary liver cancer than in other liver diseases. A rise in level seems to reflect the extent of liver regeneration in liver diseases other than primary cancer. More extensive studies will be needed to establish the consistency and possible diagnostic significance of a correlation between the extent of the regenerative response and the α-fetoprotein level in man.

GASTROINTESTINAL DISEASES

ESOPHAGUS

6050 MEASUREMENT OF GASTRO-OESOPHAGEAL ACID REFLUX: ITS SIGNIFICANCE IN HIATUS HERNIA. *(E.)* Lichter, I. (Univ. Otago Med. Sch., Dunedin, New Zealand). *Br. J. Surg.* 61(4):253-258, 1974.

Gastroesophageal reflux may be responsible for the development and symptoms of esophageal damage. Demonstration of reflux by radiography or by conventional pH studies is not, however, always correlated with disability. This unpredictability may be accounted for by the observation that during the day refluxed material is rapidly cleared from the esophagus by swallowing, while during sleep little swallowing occurs. To explore the hypothesis that reflux during sleep is the important factor, prolonged intraesophageal pH studies were carried out and a method was developed for quantifying nocturnal gastroesophageal reflux. The investigation showed that persistence of acid within the esophagus is associated with prolonged periods during sleep when no swallowing occurs. Measurements of nocturnal intraesophageal pH were made in 41 patients with symptomatic sliding hiatus hernia. In 12 patients with mild symptoms, the duration of reflux measured by this index did not exceed 15 min, with 1 exception, and no patient had esophagitis. In 10 patients with moderate symptoms, reflux did not exceed 1 hr, with 1 exception, and mild to moderate esophagitis was present in 4 cases. Nineteen patients had severe symptoms; in all but 1 the period of reflux was in excess of 1 hr, and esophagitis was found in 13. The results suggest that it is patients in whom the esophagus is bathed in reflux fluid for long periods during sleep who suffer symptoms or who are at risk from future complications of reflux.

6051 ENDOSCOPY OF THE ESOPHAGUS IN SCLERODERMA. REPORT OF 20 CASES. *(Fr.)* Petite, J. P.; Chaput, J. C.; Gueroult, J. N.; Guerre, J.; Housset, E. (Broussais Hosp., Paris, France). *Ann. Gastroenterol. Hepatol.* 9(4):311-318, 1973.

Endoscopic examinations of the esophagus were performed on 26 patients (21 women and 5 men, aged 39-68 yr; mean age 56 yr) with clinical symptoms of scleroderma. The most common symptoms were Raynaud's phenomenon (26 cases), sclerodactylia (25 cases), telangiectasia (18 cases), and ulceration or amputation of the fingers (16 cases); only 3 patients had multiple visceral involvement. In 20 patients no peristaltic contractions were observed in the lower 2/3 of the esophagus, and water remained in the esophagus for more than 30 sec after instillation of a few ml into the lower esophagus while the patient was lying down. Gastroesophageal reflux or a permanently open cardia was found in 12 patients and was associated with a small hiatus hernia in 4. Peptic esophagitis was present in 7 cases, and peptic stenosis of the lower esophagus in 3. Only 9 patients had clinical symptoms referable to the esophagus: dysphagia was present in 7, and 6 had a syndrome compatible with gastroesophageal reflux. Radiological examinations of the esophagus, performed on 25 patients, revealed disturbances in esophageal motor activity (19 cases), gastroesophageal reflux (10), hiatus hernia (3), and peptic stenosis (3). No radiological abnormalities were found in 6 patients. Excellent agreement between radiological and endoscopic findings was obtained for esophageal motor activity and peptic stenosis, but peptic esophagitis was diagnosed only by endoscopy. Although esophageal lesions were more severe among patients with visceral involvement (2 of 3 had peptic esophagitis), outline searches for disturbances in esophageal motility in patients with Raynaud's phenomenon would facilitate early diagnosis of scleroderma.

STOMACH

6070 THE ROLE OF MUCOSAL BLOOD FLOW IN THE PATHOGENESIS OF STRESS ULCERS. *(E.)* Schellerer, W. (Surg. Clin. Polyclin., Univ. Erlangen, Germany). *Acta Hepatogastroenterol* 21(2):138-141, 1974.

Local pO_2-tension was studied as an indicator of perfusion in dogs and male SPF-Wistar rats. In 10 dogs without hypoxia and with normal circulatory behavior, the blood flow in the splenic artery was correlated with the local pO_2-tension in the area of the gastric mucosa supplied by the artery. There was a positive correlation between reduced blood flow, resulting from the narrowing of the splenic artery, and the measured oxygen tension in the tissues. In restrained control rats, focal mucosal necrosis and defects of different depths were apparent within 24 hr of restraining stress. pO_2 was lower in stressed animals and the degree of the lesion was positively correlated with the reduced pO_2. Adrenalectomy alone resulted in a lower pO_2 and in similar focal mucosal lesions; additional immobilization produced greater changes. Stressed sham-operated rats showed the same changes as stressed controls.

6071 DETERMINATION OF THE INDIVIDUAL SENSITIVITY OF STOMACH CARCINOMAS TO 5-FLUOROURACIL FROM PARAMETERS OF RESPIRATION AND GLYCOLYSIS. *(Rus.)* Gnatyshak, A. I.; Shiian, D. N. (L'vov Med. Inst., USSR). *Vrach. Delo* (5):108-111, 1974.

Freshly prepared sections from 76 gastric carcinomas were incubated in the Warburg apparatus with and without 5-fluorouracil (12.5 mg/ml medium), and the rate of respiration was measured at 37 C and pH 7.4 for 2 hr. After treatment with 7% trichloroacetic acid, Ryan's technique was used to determine the concentration of lactic acid in 1 ml of medium. On the basis of these results, tumors were classified into 3 categories: (1) sensitive to 5-fluorouracil (respiration and glycolysis decreased by 60% or more, 20 tumors), (2) slightly sensitive (respiration and, in most cases, glycolysis decreased by 40-59%, 22 tumors), and (3) resistant (decreased respiration and, in some cases, glycolysis by less than 40%, 34 tumors). Sensitive tumors consisted primarily of adenocarcinomas (14 of 20), 3 scirrhous carcinomas, and no colloid carcinomas. Of the 34 resistant tumors, 12 were adenocarcinomas, 14 were scirrhous carcinomas, and 7 were colloid carcinomas. Diffuse and infiltrating carcinomas were more resistant to 5-fluorouracil than tumors with limited forms of growth. The sensitivity of the primary tumor was not appreciably affected by development of regional lymph node metastases or by its site. Tumors staged at T2 were more sensitive to 5-fluorouracil than those staged as T3. Follow-up studies made after 2 yr in 49 patients who had been given 5-fluorouracil revealed a correlation between the results of the *in vitro* study and the outcome of chemotherapy *in vivo*.

6072 LATE HYPOGLYCEMIA IN PATIENTS FOLLOWING VAGOTOMY AND PYLOROPLASTY. *(E.)* Wiznitzer, T.; Shapira, N.; Stadler, J.; Ayalon, D.; Harrell, A. (Ichilov Hosp., Tel-Aviv, Israel). *Surg.* 59(4):229-232, 1974.

Variations in plasma insulin and blood glucose levels after p.o. administration of 150 cc of 50% glucose (75 g) were studied in 24 patients following vagotomy and pyloroplasty for duodenal ulcer and in 10 normal control subjects. Following a test meal, 17 patients developed marked hypoglycemia which was asymptomatic in 11. The highest and lowest insulin and glucose levels differed significantly from those found in the controls. Individual glucose and insulin levels showed a close and constant relation and no significant difference between groups was found in the insulinogenic index. These results indicate that under a maximal stimulus, such as the test meal administered, patients are prone to develop hypoglycemia following vagotomy and pyloroplasty in the same way as they do after partial gastrectomy.

6073 HISTOAUTORADIOGRAPHIC APPROACH TO GASTROINTESTINAL TUMORS. I. STUDY OF A GASTRIC LEIOMYOMA WITH $^{35}SO_4$ AND ^{35}S-CYSTEINE. *(Fr.)* Cornet, A.; Bescol-Liversac, J.; Leperchey, F. (Laennec Hosp., Paris, France). *Sem. Hop. Paris* 49(13):911-914, 1973.

On the basis of histological and autoradiographic studies, tissue in a leiomyoma was classified into 3 different types. In the autoradiographic study, tumor fragments were incubated in oxygenated physiological saline containing $Na_2{}^{35}SO_4$ (50 μCi/ml) or ^{35}S-cysteine (5 μCi/ml) for 2 hr at 37 C. Ordinary adult smooth muscle tissue (type 1) incorporated only moderate amounts of $^{35}SO_4$ and ^{35}S-cysteine. Histologically, type (2) was characterized by tissue resembling embryonic smooth muscle tissue or schwannomas. Cells had few myofibrils and less acidophilic sarcoplasm than those belonging to type (1). Interstitial spaces surrounding these differentiating cells contained large amounts of acid mucopolysaccharide which incorporated large amounts of $^{35}SO_4$ and very little ^{35}S-cysteine. Type (3) tissue contained very thick fibers resembling certain smooth muscle fibers in invertebrates or in the wall of the human ureter. These fibers were provided with myofibrils arranged in bundles. Type (3) tissue incorporated little $^{35}SO_4$, but the sarcoplasm incorporated ^{35}S-cysteine rapidly. It is concluded that morphological variations observed in leiomyomas may correspond to different stages in the histogenesis of smooth muscle tissue.

6074 INTESTINAL IMMUNOGLOBULINS IN PRENICIOUS ANEMIA. *(E.)* Soltoft, J. (Gentofte Univ. Hosp., Copenhagen, Denmark). *Am. J. Dig. Dis.* 19(7):623-625, 1974.

Immunohistochemical investigation of gastric, jejunal, and rectal mucosal biopsies and the quantitation of immunoglobulin in jejunal juice and saliva were carried out in 8 patients (50-82 yr) with pernicious anemia, 4 under treatment with vitamin B_{12}, and 2 with additional diabetes mellitus. A slight increase of the jejunal IgG-containing cells and a decrease of IgA cells were the only abnormal findings outside the stomach, which showed grossly abnormal biopsies with a marked increase of IgG cells and a slight decrease of IgA cells. In addition, there was increased content of all immunoglobulins in the interstitial tissue. The data suggest that in pernicious anemia, no defect in the secretory immune system in mucosa remote from the stomach is present.

6075 RADIOLOGICAL EXAMINATION OF THE STOMACH AND DUODENUM AFTER PYLOROPLASTY. *(Fr.)* Lallemand, D. (St. Vincent de Paul Hosp., Paris, France). *Ann. Gastroenterol. Hepatol. (Paris)* 9(5):467-476, 1973.

An analysis was made of more than 100 radiocinematographic examinations of the upper gastrointestinal tract in patients who had undergone Heinecke-Mikulicz pyloroplasty and total or selective vagotomy. Although normal morphological features varied greatly from one patient to another, the pylorus had usually disappeared due to telescoping of the antrum and duodenum, and 2 recesses or symmetrical pseudodiverticula appeared in the lesser curvature and greater curvature, resp. Barium swallow examinations revealed gastric and duodenal stasis, which was evident in about 3/4 of these patients during the first month after surgery and gradually disappeared. Stasis was rare after the first year and was never associated with any organic obstruction. Radiologically detected sequelae included postoperative stenosis above the pyloroplasty which was associated, in 1 case, with a recurrent gastric ulcer; recurrent gastric and duodenal ulcers; and gastrointestinal dyskinesia. None of these patients developed gastric cancer after pyloroplasty. In some cases radiological evidence of dyskinesia was associated with clinical symptoms, but too few patients were studied to establish a cause and effect relationship. However, corrective surgery had to be performed on 1/2 of the patients who showed barium retention at the site of the pyloroplasty, between the antrum and duodenum. At surgery, the vagotomy was found to be incomplete or the area between the antrum and duodenum was too narrow. The absence of a duodenal blocking zone was another radiological finding occasionally associated with postoperative sequelae. In these cases barium passed rapidly from the stomach into the small intestine under the force of gravity, without the occurrence of gastric or duodenal contractions. True gastric antiperistalsis, which has previously been reported only in dogs, was observed for the first time in man in 3 of these patients.

6076 PSEUDOLYMPHOMATOUS GASTRITIS (PSEUDOLYMPHOMA OF THE STOMACH): ANATOMICAL AND RADIOLOGICAL CORRELATIONS. *(Fr.)* Meagher-Villemure, K.; Gareau, R.; Levesque, H. P. (Hotel Dieu, Montreal Canada). *Union Med. Can.* 103(4):717-721, 1974.

A 43-yr-old man had a 1-yr history of frequent vomiting of food and bile after meals and had lost 45 pounds in 3 months. Although gastroscopy showed neoplastic-like infiltration in the lesser curvature, a biopsy revealed only chronic inflammation of the gastric mucosa. Mucography showed definite thickening of the mucosa due to infiltration. Infiltrates caused contraction of the lesser curvature, made it rigid, and obliterated the angular fold. The mucosa was raised in some places and multiple superficial ulcerations measuring 3-10 mm in diameter were also detected. Examination of material removed at partial gastrectomy revealed a lesion measuring 8.5 x 7.5 cm which was devoid of folds and showed severe congestion along its periphery. In addition to peripheral erosions and ulcers, histological examination demonstrated signs of progressive gastritis associated with submucosal sclerosis. This is the 9th case of pseudolymphomatous gastritis diagnosed at 1 hospital in a 12-yr-period. These 9 patients consisted of 4 men and 5 women, aged 42-66 yr (mean 58 yr). Patients had clinical symptoms for 2 months to 8 yr before surgery. Gastroscopic diagnoses consisted of malignancies (4 cases), gastritis (3 cases), and benign ulcer (1 case).

6077 MECHANISM OF STRESS ULCER. III. EFFECTS OF HEMORRHAGIC SHOCK ON ENERGY METABOLISM IN THE MUCOSA OF THE ANTRUM, CORPUS, AND FUNDUS OF THE RABBIT STOMACH. *(E.)* Menguy, R.; Masters, Y. F. (Univ. Rochester Sch. Med., Den., N.Y.). *Gastroenterology* 66(6):1168-1176, 1974.

Since only the gastric fundus and corpus exhibit stress ulceration associated with blood loss, this study measured the energy deficit in the gastric mucosa of the antrum as compared to the fundus and corpus. Hemorrhagic shock was induced in male albino rabbits by either a single bleed or controlled hypotension method so that arterial blood pressure reached a mean level of 30 mm Hg. ATP levels and levels of ATP + ADP + AMP were significantly higher in the corpus mucosa than in the antrum and fundus of 11 controls which were not bled. In the single bleed condition the antrum mucosa had less decrease in ATP levels and less increase in AMP levels than in the corpus and fundus mucosa after 15 min of hypotension. One hr after the induction of shock, appreciable recovery in energy metabolism in the mucosa coincident with improvement in hemodynamic conditions was evident. With controlled hypotension, there was a much more rapid dephosphorylation of adenine nucleotides in corpus and fundus than in the antrum. Quantitatively, the changes were more severe than after a single bleed: greater drop in ATP + ADP and AMP, particularly in the corpus and fundus, and lower levels of ADP and AMP. Analysis of other substrates showed pyruvate levels lower and lactate rates higher in parietal cell mucosa (corpus and fundus) than in the antrum. The data here indicate that during severe hemorrhagic hypotension, antral mucosal tissue can sustain its energy metabolism at appreciably higher levels than the mucosa of the proximal regions of the stomach. The breakdown of adenosine phosphates in the corpus and the fundus was accompanied by an increase in glycolytic flux greater than that taking place in the antral mucosa. In the antrum, a slowly appearing energy deficit was accompanied by a slow glycolytic flux.

6078 GASTRIC INHIBITORY POLYPEPTIDE. RESPONSE TO ORAL GLUCOSE AFTER VAGOTOMY AND PYLOROPLASTY. *(E.)* Thomford, N. R.; Sirinek, K. R.; Crockett, S. E.; Mazzaferri, E. L.; Cataland, S. (Ohio State Univ. Hosp., Columbus). *Arch. Surg.* 109 (2):177-182, 1974.

Gastric inhibitory polypeptide, immunoreactive insulin, and glucose levels in response to glucose p.o. were determined in 10 patients with vagotomy and pyloroplasty and in 21 normal subjects. The truncal patients had the expected early and exaggerated increase in mean serum glucose with a subsequent decline to a level below fasting. The early mean gastric inhibitory polypeptide response was similarly elevated and paralleled the glucose response. The early mean serum immunoreactive insulin of the patients was greater than that of normal subjects, but only at 30 min was the difference statistically significant. Since gastric inhibitory polypeptide is known to be insulinotropic, the results of this study suggest that its role in the enteroinsular axis is magnified after vagotomy and pyloroplasty. The gastric inhibitory polypeptide may be in part responsible for the postprandial hypoglycemia recognized clinically as the late phase of the dumping syndrome.

6079 COLLECTION OF CHOLECYSTOGRAPHIC CONTRAST MATERIAL IN A LARGE ULCERATING LEIOMYOMA OF THE STOMACH. *(E.)* Perrin, R. L.; Boehnke, M. (Montefiore Hosp., Pittsburgh, Pa.). *Gastroenterology* 66 (4):601-603, 1974.

A 64-year-old man was hospitalized with a history of left lower leg thrombophlebitis and enlarging varicose veins. His hematocrit was 25.2%. There was no history of previous peptic ulcer disease and no symptoms of gastrointestinal discomfort or tarry stools. Guaiac positive stools were noted on digital rectal examinations. After two oral cholecystograms, a faint opacification of the gallbladder with a large amorphous collection of residual cholecystographic contrast material (ipodate) in the left upper abdominal quadrant was revealed. An upper gastrointestinal series showed a large ulcer crater with a broad-based, sharply defined, patent neck on the posterior wall of the body of the stomach. A prominent soft tissue mass surrounded the ulcer crater. Pathologic examination revealed a large subserosal and intramural leiomyoma ulcerating the gastric mucosa. The lack of mitotic activity seemed to indicate a benign rather than malignant tumor. The amorphous collection of contrast material in this case was most likely due to the persistent recumbent position at bedrest which allowed the contrast material to enter the leiomyoma. The material then became entrapped because of the lack of ambulation after the oral ingestion of the cholecystographic tablets.

STOMACH

Peptic Ulcers

6103 PROSTAGLANDIN E IN PEPTIC ULCER DISEASE. *(E.)* Hinsdale, J. G.; Engel, J. J.; Wilson, D. E. (Dept. Med., Univ. Illinois, Chicago). *Prostaglandins* 6(6):495-500, 1974.

Prostaglandin E_1 and E_2 inhibit gastric secretion *in vivo* and *in vitro* under a variety of conditions, but it is not known whether these compounds play a role in normal gastric secretory physiology or in the pathophysiology of peptic ulcer. Six patients with documented duodenal ulcer and 6 normal adults were studied under basal conditions and during gastric secretory stimulation with i.m. betazole (1.5 mg/kg). Prostaglandin E in plasma and gastric juice was measured by radioimmunoassay. The prostaglandin E was significantly higher in the plasma of normal volunteers both in the basal state and during stimulation. Gastric juice prostaglandin E was also significantly higher in the controls during the basal state but the difference disappeared during stimulation. The relative deficiency of prostaglandin E in the ulcer group may indicate a role for prostaglandins in the pathophysiology of gastric hypersecretion.

6104 EFFECT OF INSULIN INJECTION ON SERUM GASTRIN CONCENTRATIONS IN DUODENAL ULCER PATIENTS AND NORMAL SUBJECTS. *(E.)* Stadil, F.; Rehfeld, J. F. (Rigshosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(2):143-147, 1974.

In 22 normal humans, the i.v. injection of 0.20 IU/kg insulin caused an increase in the serum concentrations of gastrin (from 26.7 ± 1.6 to 34.6 ± 3.9 pmol/liter) during gastric aspiration. The increase lasted for 1 hr. In 65 patients with duodenal ulceration, the gastrin concentrations increased from 30.1 ± 1.8 to 44.9 ± 3.0. The increase lasted for more than 1.5 hr. The response was significantly greater in the ulcer patients. Basal gastrin levels did not differ significantly between the two groups. In the normal subjects, gastric aspiration did not significantly change the basal gastrin concentrations; however, the insulin-induced increase in gastrin output was increased by aspiration, confirming the inhibitory action of low intragastric pH on the antral mucosa. The insulin-induced increase in gastrin output was also increased without aspiration, and the duration of the increase was not shortened. The data indicate that an intragastric pH of 1.0 to 1.5 does not abolish the gastrin response to insulin.

6105 PSYCHIATRY SERIES NO. 10: PERSONALITY AND DUODENAL ULCER. *(E.)* Apter, A.; Hurst, L. A. (Dept. Psychol. Med., Univ. Witwatersrand, Johannesburg, S. Africa). *S. Afr. Med. J.* 47(44):2131-2133, 1973.

Personality traits measured in 30 duodenal ulcer patients at a Johannesburg hospital were compared with those of 30 controls who had surgical conditions of comparable severity. The study was augmented by transcultural comparison of 50 male duodenal ulcer outpatients in Israel. There were no significant differences between the 2 groups of ulcer patients and controls in overall anxiety on the IPAT Anxiety Scale or in psychoticism, neuroticism, or extraversion as measured by the Maudsley Personality Inventory. Psychiatric histories obtained for Johannesburg ulcer patients suggested that pain may have decreased some basic drives. The results support recent views of psychosomatic illness as a reaction to stress, independent of static personality traits or specific emotional conflict.

6106 PEPTIC ULCER DISEASE IN THE TRANSPLANT RECIPIENT. *(E.)* Spanos, P. K.; Simmons, R. L.; Rattazzi, L. C.; Kjellstrand, C. M.; Buselmeier, T. J.; Najarian, J. S. (Dept. Surg., Univ. Minnesota, Minneapolis). *Arch. Surg.* 109(2):193-197, 1974.

Of 377 patients, 30 gave evidence of peptic ulcer prior to renal transplantation over a 5-yr period. Prophylactic vagotomy with pyloroplasty or antrectomy was performed on 19 of these patients prior to transplantation, and 14 of them were still well with transplants 7-61 months later; only 3 of these patients had posttransplant ulcer complications. No planned prophylactic operation was performed in 11 of the 30 peptic ulcer patients; 9 of these patients bled in the pre- or posttransplant period. Only 3 of 347 patients without pretransplant evidence of ulcer bled in the posttransplant period. None of the patients with vagotomy-antrectomy showed evidence of recurrent bleeding, but patients with active ulcer disease pretransplant sometimes had recurrences after vagotomy-pyloroplasty. These results indicate that pretransplant correction of the ulcerogenic tendency should be carried out and that antrectomy should be considered if active ulcers are present in the uremic transplant candidate.

6107 CIRCADIAN VARIATION OF PROSTAGLANDIN E (PGE) PRODUCTION IN HUMAN GASTRIC JUICE. *(E.)* Tonnesen, M. G.; Jubiz, W.; Moore, J. G.; Frailey, J. (Univ. Utah Coll. Med. Salt Lake City). *Am. J. Dig. Dis.* 19(7):644-648, 1974.

Prostaglandin E output in human gastric juice was determined by radioimmunoassay and correlated with gastric acid secretion in 10 normal subjects and 10 patients with duodenal ulcer. Prostaglandin E and acid outputs were higher in patients with peptic ulcer. Although not statistically significant, these changes were probably secondary to changes in gastric juice volume. A circadian rhythm of gastric Prostaglandin E production was observed in normal subjects with high output at midday, a spike at midnight, and low output in the early morning, in phase relationship to the circadian rhythm of gastric acid secretion. Disruption of Prostaglandin E and acid rhythms was found in ulcer patients. This study does not support the concept that prostaglandin deficiency may be an etiological factor in peptic ulcer disease. Nonetheless, a heretofore unrecognized disruption in gastric rhythm may prove to be of physiologic significance.

6108 CHANGES IN THE GASTRIN SECRETING "G" CELLS IN PEPTIC ULCER. *(It.)* Marzola, A.; Fabris, G.; Beltrami, C. A.; Nenci, I. (Inst. Pathol. Anat. Histol., Univ. Ferrara, Italy). *Riv. Patol. Clin. Sper.* 13(1/2):21-36, 1972-1973.

Quantitative evaluations of G cell populations and their ultrastructure were performed on material biopsied from the gastric antrum of 37 gastrectomized patients. These consisted of 12 patients with gastric ulcers, including 3 with healed ulcers; 10 with duodenal ulcers; 4 with primary adenocarcinomas in the lesser curvature; 1 with an anastomotic ulcer; and 10 with no evidence of peptic ulcer or gastric neoplasm. The number of G cells revealed by staining with hematoxylin-lead, was increased by a mean of about 35% in patients with recent uncomplicated gastric ulcers and was decreased by about 20% in those with duodenal ulcers. The decrease in G cells was pronounced in about half the patients with duodenal ulcers, while the results varied greatly in the other half. Because of the small number of patients examined, values obtained in patients with other diseases are not significant. However, the mean number of G cells was decreased by about 75% in patients with healed gastric ulcers and by about 38% in patients with gastric adenocarcinoma. The number of granulations, an indication of the gastrin content of the antral mucosa, correlated roughly with the number of cells per unit area, but values were high for uncomplicated gastric ulcer and low for duodenal ulcer. Electron microscope examinations with indirect immunofluorescence and hematoxylin-lead staining showed intense stimulation of gastrin production in gastric ulcer and gastrin storage in duodenal ulcer. The small number of G cells found in patients with healed gastric ulcers and gastric adenocarcinomas is attributed to severe antral gastritis and mucosal atrophy involving the endocrine cells.

6109 PREVENTION OF BILE REFLUX-INDUCED ACUTE GASTRIC ULCERATION IN THE RAT BY CHOLESTYRAMINE. *(E.)* Mersereau, W. A.; Hinshey, E. J. (Montreal Gen. Hosp., Canada). *Ann. Surg.* 179(6): 833-888, 1974.

The role of bile salts and refluxed duodenal content in the pathogenesis of acute gastric ulcers was examined in shocked Sprague-Dawley rats. Duodenal reflux was induced in duodenum-ligated animals by infusion of fluid through a catheter introduced just proximal to the ligation. For control animals, the duodenal contents were flushed into the stomach with 1 ml of tap water or placebo preparation. For experimental animals, 33 mg cholestyramine (Questran) was used in 1 ml of tap water. Fifteen minutes later, 5 ml of a 100 mEq/1 HCl solution were instilled into the stomach through the duodenal catheter and the animals were shocked by reducing the blood pressure to 20 mm Hg for 10 min by bleeding through a cannulated carotid artery. The shed blood was then reinfused, 0.1 ml colloidal carbon was infused into a right saphenous vein to mark tissue injury, and the animals were allowed to live 10 min longer before sacrifice. The stomachs were finally flushed and fixed with formalin. Following the duodenal reflux and shock, all of 8 control rats showed extensive ulceration as revealed by hemorrhage and accumulation of colloidal carbon in damaged vessels at the base of the ulcers. Of the 6 experimental rats, five showed inhibition of ulceration, the 6th showing only slight ulceration. Rats whose bile ducts were ligated 2 days before the reflux and shock procedures also failed to show extensive ulceration. These results suggested that the presence of bile salts in refluxed duodenal contents were responsible for breaking a normal barrier to ulceration. To further demonstrate barrier-breaking action in the stomach, *ex vivo* gastric chambers were prepared in rats, and experiments similar to the preceding *in vivo* tests were carried out except that bovine sodium taurocholate and sodium sulphate were used in place of refluxed duodenal contents. It was found that the ulcerative action due to these two barrier-breaking agents could be prevented by prior introduction of cholestyramine.

Cholestyramine also inhibited the usual rapid depression of the transmucosal potential difference (PD) produced by both of these agents. This PD was measured between the femoral vein and the chamber contents using catheters filled with 4% agar in saturated KCl. It was concluded that cholestyramine protects gastric mucosa from ulceration by blocking the barrier-breaking action of bile salts in duodenal chyme.

6110 FOLLOW-UP STUDY OF 100 PATIENTS WITH GIANT GASTRIC ULCER. *(E.)* Jensen, H. E.; Fenger, C.; Amdrup, E.; Christiansen, P.; Lindskov, J.; Nielsen, J.; Damgaard Nielsen, Sv. Aa. (Munic. Hosp., Copenhagen, Denmark). *Chir. Gastroenterol.* 7(4):397-405, 1973.

Clinical symptoms, complications, the incidence of malignancy, and mortality were investigated with regard to ulcer size in a consecutive series of 701 patients with stomach ulcers. Of these patients, 100 (14%) had ulcers judged from radiological and/or pathological examination to be larger than 3 cm in diameter and 601 patients had smaller ulcers. The sex ratio was similar in both groups, but there were significantly more patients less than 45 yr old among those with giant ulcers than among patients with smaller ulcers. The duration of symptoms was about the same in both groups. Although excessive weight loss (more than 10 kg in 6 months) was similar in both groups, 60% of patients with giant ulcers and only 45% of those with small ulcers lost weight. Patients with giant ulcers had more severe pain which often radiated, especially to the back, and this pain was less likely to be relieved by antacids or food. Although the bleeding frequency was similar in both groups, perforation, hemorrhagic shock, and radiological evidence of malignancy were significantly more frequent among patients with giant ulcers. The operative mortality was similar in both groups, but postoperative complications were more common among patients with giant ulcers. This was particularly true of anastomotic leakage, intraperitoneal abscess, pancreatitis, wound rupture, and persistent gastric retention. Over the follow-up period, which ranged from 5-15 yr (average 8 yr), 47% of the patients with giant ulcers and 39% of those with small ulcers died. The incidence of gastric carcinoma was 3% among patients with small ulcers and 6% among those with giant ulcers. Neither of these differences was significant. The incidence of anemia was higher in patients with giant ulcers, but low serum iron levels were found in both groups. Of 385 patients with gastric carcinoma treated over the same period, 23 had ulcers larger than 3 cm in diameter. These results suggest that in patients with giant gastric ulcers a nonsurgical approach should be followed until surgery is required. A surgical approach should not be adopted just because the ulcer is large.

SMALL INTESTINE

6130 CONGENITAL DUODENAL WEB IN AN ADULT. *(E.)* Mackay, A. G.; Elo, D. E.; Teines, H. (Univ. Vermont Coll. Med., Burlington). *Am. Surg.* 40(6): 355-359, 1974.

A 72-yr-old woman presented with a long history of epigastric pain and occasional vomiting and recent weight loss. A roentgenogram of the upper gastrointestinal tract showed a large obstructed stomach. Through a gastroduodenal incision made to explore the pylorus and duodenal areas, a mucosal web nearly closing the duodenum in the second portion was seen, located about 3 cm above, or proximal to the ampulla of vater. The eccentric opening in the web was 5 mm in diameter. The congenital web was excised and a gastroduodenostomy performed to drain the duodenum beyond the point of former obstruction. Symptoms of duodenal webs include postprandial fullness, epigastric cramping pain, nausea and vomiting. Epigastric peristalsis may be seen in about 25% of the cases. Roentgenographic examination, especially the cine-fluoroscopic studies, are helpful in diagnosis, most often showing an enlarged distended stomach with distended proximal duodenum, ending smoothly and abruptly near the level of the ampulla. Treatment of choice is duodenotomy with excision of the web. Gastroenterostomies can lead to problems with a blind loop syndrome. The distal duodenum must be explored since webs may be multiple. The most likely explanation for the delay of development of symptoms with duodenal webs in adults is intermittent obstruction of the duodenum by food particles, with gradually increasing distention of the proximal duodenum. This causes faulty mechanical functioning of the bowel wall with peristalsis of the duodenum becoming unable to push through this narrowed opening.

6131 DUODENAL PERFORATION: A COMPLICATION OF NEONATAL NASOJEJUNAL FEEDING. *(E.)* Boros, S. J.; Reynolds, J. W. (Children's Hosp., St. Paul, Minn.). *J. Pediatr.* 85(1):107-108, 1974.

Nasojejunal alimentation was begun in a 60-hr-old male infant. A polyvinyl feeding tube (36 inch radio-paque Premature Infant Feeding Tube) was passed into the proximal jejunum and position confirmed. After 8 hr the infant tolerated feedings to full strength Isomil (20 cal/oz) at a rate of 2 ml/hr and the infusion rate was slowly advanced. At 80 hr of age, frequent episodes of apnea with bradycardia were noted. After 16 hr of increasingly frequent apnea spells, a No. 3 Portex tube was passed into the posterior nasopharynx and 1.5-2 cm of end-expuratory pressure applied. At 102 hr, the abdomen became distended and green-stained formula was aspirated from the stomach. Radiograms showed the nasojejunal tube had slipped into the second portion of the duodenum.

Assuming the proximity of the tube to the pylorus was causing the reflux and gastric distension, the tube was advanced an additional 3 cm and feedings continued. At 107 hr of age, episodes of apnea with bradycardia recurred. Radiographs of the chest and abdomen showed only a change in the position of the nasojejunal tube, extended 2-3 cm directly caudal to its previous position in the duodenum. By 122 hr the child required constant ventilation with bag and mask. Abdominal roentgenograms showed a large pneumoperitoneum. Feedings stopped and gastric suction was begun. Laparotomy revealed perforation of the third portion of the duodenum with 2-3 cm length of feeding tube extended through the perforation into the abdominal cavity. Death occurred at 134 hr of age. This case demonstrated the trait of polyvinyl feedings tubes to change dramatically after only a short time in the lumen of the bowel. The tube becomes hard and very stiff, after as little as 6-8 hr. Such a tubing could easily perforate the bowel wall. It is suggested that nasojejunal tubes not be repositioned, but rather removed and replaced.

6132 MESENTERIC ADENITIS: INTESTINAL OBSTRUCTION AND INFARCTION. ONE CASE. *(Sp.)*

Escriva, J.; Cortes Encinas, F.; Perez Clavijo, J. M. (La Fe Munic. Sanit., Valencia, Spain). *Rev. Esp. Enferm. Apar. Dig.* 43(1):75-82, 1974.

A 7-yr-old boy who presented with periumbilical pain, severe vomiting, fever, and constipation had acute diffuse mesenteritis associated with acute mesenteric lymphadenitis at laparotomy. Complete ileus was caused by compression of the lymph nodes and adhesions in the distal ileum. Within 1 yr after surgery to relieve intestinal obstruction, the patient was rehospitalized with repeated vomiting and abdominal pain. A scout film of the abdomen showed dilatation of a loop of the small intestine on the left. A repeat film of the abdomen, taken after abdominal pain had intensified, showed more pronounced dilatation of the small intestine. Both intestinal obstruction and mesenteric infarction were found at surgery. The patient made an uneventful recovery after resection of 40 cm of the small intestine and end-to-end anastomosis. This case illustrates the difficulty of diagnosing these conditions because of nonspecific symptoms and radiological findings.

6133 LYMPHOID HYPERPLASIA OF THE ILEUM. ALWAYS BENIGN DISEASE? *(E.)*

Danis, R.K. (Cardinal Glennon Mem. Hosp. Child., St. Louis, Mo.). *Am. J. Dis. Child.* 127(5):656-658, 1974.

In 6 cases of lymphoid hyperplasia and associated pseudopolyposis (5 boys and 1 girl, aged 2-12 yr) the lesions were sharply limited in the distal 10 cm of ileum in 4 cases and in 1 additional case showed extension into the cecum. The sixth case showed isolated involvement in an 8-cm segment of midjejunum. Surgery was necessary in 5 cases. The remaining case was roentgenographically diagnosed and treated nonoperatively. The clinical course of this condition is varied. Symptoms are usually intermittent and not severe. Spontaneous disapperance over a period of weeks to months is expected. Roentgenographic identification usually allows management by observation in mildly symptomatic patients; or management by steroid therapy in those with major complications such as significant hemorrhage or reducible intussusception. In patients with life-threatening symptoms, surgical exploration is necessary. The lesion presents most often as a sharply limited segmental abnormality of the intestine. The bowel is thickened and has an irregular polypoid consistency. On biopsy examination, marked lymphoid hyperplasia in the mucosa and submucosa with little evidence of adjacent inflammation and a normal overlying mucosa confirm diagnosis.

6134 "LOWER" GASTROINTESTINAL TRACT HEMORRHAGE: NEW CONCEPTS BASED ON ARTERIOGRAPHY. *(E.)*

Casarella, W. J.; Galloway, S. J.; Taxin, R. N.; Follett, D. A.; Pollock, E. J.; Seaman, W. B. (Columbia Coll. Phys. Surg., New York, N. Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 121(2):357-368, 1974.

In 60 consecutive cases of acute rectal hemmorrhage seen over a 5-yr period, arteriography demonstrated the bleeding lesion in 40. All but 1 of these patients were ultimately operated on for removal of the specific bleeding point. In the remaining patient, massive bleeding from a duodenal ulcer was permanently controlled by vasopressin infusion. Colonic diverticulosis was the most common cause of rectal hemorrhage (17 cases) and was present in patients aged 55-84 yr. Most bleeding colonic diverticula were located to the right of the splenic flexure. Arteriography demonstrated that other causes of hemorrhage were arterivenous malformation (4), aortic stenosis and arteriovenous malformation of the right colon (3), duodenal ulcer (4), carcinoma of the colon (3), Meckel's diverticulum (2), jejunal diverticula (2), arteriovenous fistula (2), and Peutz-Jeghers syndrome, local rectal trauma, and ischemic colitis (1 each). In 2 of the 3 elderly patients with aortic stenosis, malformation of the right colon was demonstrated by magnification roentgenograms. One of the arteriovenous fistulas formed after closure of a transverse colostomy for obstructing sigmoid diverticulitis; the other developed in a patient with a gunshot wound of the abdomen. In this series, duodenal ulcers produced a clinical syndrome indistinguishable from lower gastrointestinal hemorrhage in 9 patients. Of the 20 patients with negative arteriograms, 5 required surgery for duodenal ulcers, 4 underwent colectomies, and 1 multiple colotomies. Ten negative patients stopped bleeding spontaneously. The findings indicate that arteriography is the diagnostic method of choice in acute lower intestinal tract hemorrhage.

6135 HYDROXYSTEARIC ACID AND DIARRHOEA FOLLOWING ILEAL RESECTION. *(E.)*

Wiggins, H. S.; Cummings, J. H.; Pearson, J. R. (Central Middlesex Hosp., London, England). *Gut* 15(5):392-395, 1974

To determine a possible cathartic action of 10-hydroxystearic acid, fecal weight and 10-hydroxystearic acid output were measured in 10 patients (5 women and 5 men, aged 36-60 yr) who complained of diarrhea after ileal resection. One series of measurements was done while all patients were on a 3-day diet of 2200 calories containing 85 g fat of which 70 g was olive oil (83.5% oleic glycerides). No relation was found between fecal weight (162-1528 g/day) and hydroxystearic acid production (0.09-9.7 g/day). In 1 patient, fecal weight decreased on the olive oil diet although the 10-hydroxystearic acid output increased to 10 times its initial value. Two other patients showed no significant changes in fecal fat output even when 10-hydroxystearic acid output increased several fold. In 3 of the 10 patients, the output of hydroxystearic acid was reduced when the dietary fat was changed to 70 g coconut oil (75% oleic acid) or to 70 g corn oil (30% oleic acid). There was no reduction in fecal weight. These studies clearly demonstrate that the severity of diarrhea following ileal resection is not related to the amount of 10-hydroxystearic acid present in stools.

6136 INTRALUMINAL DUODENAL DIVERTICULUM. A RARE CAUSE OF ACUTE PANCREATITIS. *(E.)*

Lawson, T. L. (George Washington Med. Ctr., Washington, D. C.) *Am. J. Dig. Dis.* 19(7):673-677, 1974.

A case report of a 14-yr-old boy with acute pancreatitis due to an intraluminal duodenal diverticulum is presented. In this patient, an initial diagnosis of appendicitis was made on the basis of acute onset of abdominal pain, anorexia, nausea, and vomiting. Laparotomy revealed a normal appendix but a large amount of serosanguinous peritoneal fluid containing 30,000 U amylase. The pancreas was edematous and hemorrhagic but there was no obvious etiology of acute pancreatitis. Postoperatively, the patient developed spiking fevers and symptoms of small-bowel obstruction. He was reexplored on the 12th hospital day and multiple adhesions were found throughout the abdomen with several loculated small abcess cavities. Six days after surgery, he was transferred to another hospital where an amylase level of 234 U was recorded. This value rose to 565 U over 2 weeks of treatment with i.v. fluid, antibiotics, and nasogastric suction. Roentgenograms showed the duodenum was dilated and partially obstructed by a large intraluminal duodenal diverticulum. At operation, a large retrogastric pancreatic pseudocyst was exposed and drained, and the membranous intraluminal diverticulum was ruptured. After further surgery to ligate a bleeding artery in the pseudocyst wall, the patient gradually improved and was discharged on the 60th hospital day. Approximately 80% of duodenal webs are located in the 2nd portion of the duodenum and related to the ampulla of Vater. In this patient, the exact site of the ampulla of Vater in relation to the attachments of the intraluminal diverticulum was not identified. Only 4 previous cases of acute pancreatitis associated with an intraluminal dudodenal diverticulum have been reported.

6137 ANGIOGRAPHIC FINDINGS IN TWO CASES OF MECKEL'S DIVERTICULUM WITH RECURRENT BLEEDING. *(Ger.)*

Friedmann, G.; Butzler, H.-O.; Wehrle, J. (Radiol. Inst., Univ. Cologne, Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 120(4):446-452, 1974.

Case reports are presented for 2 children, a 5.6-yr-old boy and a 12-yr-old girl, who developed recurrent melena. Seldinger's technique was used to demonstrate the superior mesentric artery. In the first case an atypical artery, several cm long, originated from the ileocolic artery and followed a corkscrew-like path with changes in its diameter. In contrast to the other arteries visualized, it remained contrasted into the venous phase and was regarded as a vitelline artery, confirming the diagnosis of Meckel's diverticulum. In the second case a deposit of contrast medium was found which remained visible into the venous phase. When this angiographic finding is associated with clinical evidence of gastrointestinal bleeding, it can be interpreted as extravasation. A Meckel's diverticulum was removed from both patients. Histological examination of both specimens showed that the diverticulum was covered, for the most part, with gastric mucosa. Ulceration and localized chronic diverticulitis was present in the first case, while a recent peptic ulcer was found in the second.

6138 HYPEROXALURIA IN PATIENTS WITH ILEAL RESECTION: AN ABNORMALITY IN DIETARY OXALATE ABSORPTION. *(E.)*

Earnest, D. L.; Johnson, G; Williams, H. E.; Admirand, W. H. (San Francisco Gen. Hosp., Calif.) *Gastroenterology* 66(6):1114-1122, 1974.

Intestinal oxalate absorption, as reflected by renal oxalate excretion, was studied in 20 normal subjects, in 15 patients (24-60 yr of age) with an ileostomy who had total colectomy for either ulcerative or granulomatous colitis, and in 11 patients (28-57 yr of age) who had ileal resection for regional enteritis. Urinary excretion of an oral load of ^{14}C-oxalate was increased in the 7 patients with extensive (≥100 cm) ileal resection, but was normal in the 4 patients with minimal (<50 cm) ileal resection. Approximately 6% of the oxalate in 100 mg of spinach was absorbed and excreted in urine by normal subjects, by ileostomy patients and by patients with minimal ileal resection. None of these experienced hyperoxaluria. However, patients with extensive ileal resection had hyperoxaluria and excreted about 30% of supplemental spinach oxalate by the urine. Despite the presence of hyperoxaluria, urinary glycolate was normal in all patients. Severe fat malabsorption was noted in all patients with extensive ileal resection. A direct relation was demonstrated between dietary fat malabsorption and urinary oxalate excretion. Increasing the dietary fat content of an otherwise constant diet further increased urinary oxalate excretion in hyperoxaluric patients. Thus it is suggested that excessive malabsorbed fatty acids may decrease the amount of intraluminal calcium available for binding with dietary oxalate and thereby facilitate abnormal oxalate absorption leading to hyperoxaluria and nephrolithiasis in patients with extensive ileal resection or disease.

6139 FAT-REDUCED DIET IN THE TREATMENT OF HYPEROXALURIA IN PATIENTS WITH ILEOPATHY. *(E.)*

Andersson, H.; Jagenburg, R. (Dept. Clin.

Nutr. Chem. Univ. Goteborg, Sweden). *Gut* 15(5): 360-366, 1974.

Thirteen patients (6 women and 7 men, mean age 38 yr.) with ileopathy were studied under metabolic ward conditions, first on a 100-g fat diet and later on a 40-g fat diet. Ten of the patients were studied after 3-27 months on a fat-reduced diet. Ten of the patients had a high urinary oxalate excretion on the high-fat diet compared with a control group. The patients with fecal fat output of more than 15 g a day showed a reduction in oxalate excretion when the fat intake was decreased; and in the follow-up study, the oxalate excretion was low in all patients except in one with a remaining steatorrhea. There was a correlation between urinary oxalate excretion and fecal output of fatty acids. It is postulated that a low intraluminal calcium ion concentration, mainly caused by the high fatty acid content, explains the hyperoxaluria. The low-fat diet, which also reduced the diarrhea and increased the urinary output, was acceptable to the patients. This diet is recommended for patients with ileopathy to reduce the risk of formation of renal calculi.

6140 ACUTE TERMINAL ILEITIS AND Yersinia INFECTION. *(E.)* Gurry, J. F. (St. George's Hosp. Med. Sch., London, England). *Br. Med. J.* 2(5913):264-266, 1974.

A case history is presented of a 12-year-old boy with pain in the right iliac fossa, together with fever, vomiting, and lack of bowel movement. Laparotomy showed free serous fluid, a thickened and slightly congested retrocecal appendix, an inflamed, erythematous, indurated 8 cm of terminal ileum with serosal hyperemia extending on to the cecum, and enlarged lymph nodes in the small-bowel mesentery. The appendix was removed, and specimens of lymph node biopsies and of free peritoneal fluid were taken. Benzylpenicillin was administered, and recovery was uneventful. Histologically the appendix showed a non-specific hyperplasia of the lymphoid follicles with moderate submucosal fibrosis. Epithelioid granulomata were not seen and there was no evidence of an acute intramural inflammatory process. The lymph nodes showed pronounced sinus hyperplasia with no epithelioid granulomata or other specific features. *Yersinia* antibody titers were diagnostic of *Y. pseudotuberculosis* infection with a type 1 titer of 1/10,240. The organism was isolated from the appendix and was sensitive to ampicillin, tetracycline, co-trimoxazole, gentamicin, and cephalothin sodium but not to sulphonamides. There was no growth of the organism from cultures of the lymph node, peritoneal fluid, or feces. The differential diagnosis includes in particular acute Crohn's disease. With acute terminal ileitis due to Crohn's disease, there may be significant past history or evidence at laparotomy or later from barium studies of other segmental intestinal involvement, usually the cecum. In all cases of acute terminal ileitis found at laparotomy, appendectomy, culture and histological examination of the resected organ, culture of free peritoneal fluid, blood, feces and urine, and serological tests for *Yersinia* are recommended. Barium studies should be performed postoperatively if Crohn's disease is suspected.

6141 HETEROTOPIC GASTRIC MUCOSA OF ILEUM CAUSING ACUTE INTUSSUSCEPTION. *(E.)* Katsube, Y.; Lebhar, N. M.; Noto, A. C.; Hughes, W. (Norwalk Hosp., Conn.). *Conn. Med.* 38(4):156-158, 1974.

A case report is presented of a 6-yr-old boy with acute intestinal intussusception secondary to ileal gastric mucosa. One week after admission for mild upper respiratory infection, the patient suddenly developed para-umbilical pain associated with nausea. The pain became cyclic and more colicky. He had intermittent bile-stained emesis and passed three diarrheal stools, then a "current jelly" stool. A clinical diagnosis of intussusception was made. Physical examination revealed a well-nourished, dehydrated child, with a slightly distended abdomen and palpable ill-defined mass in the umbilical area. Roentgenograms showed marked dilation of small intestinal loops and air-fluid levels. Emergency barium enema examination revealed an intussusception in the hepatic flexure during initial fluoroscopic examination. The intussusception was reduced proximally to the region of the ileocecal valve during fluoroscopy. When meniscus sign was observed on x-ray, standard radiographic techniques were used but reduction was incomplete: postevacuation films demonstrated a large, soft issue density opposite the mid ascending colon. Following administration of i.v. fluids for correction of dehydration, emergency surgery was performed. No intussusception was found at laparotomy, indicating spontaneous reduction, but many enlarged lymph nodes were observed in the mesentery of the bowel. About 30 cm proximal to the ileocecal valve there was slight protrusion beginning from the mesenteric border of the lateral wall of the ileum. Within the protrusion there was a pink, polypoid mass 0.9 cm wide and 2.0 cm long. The elliptical mass was fixed to the ileal wall. The mass was excised, the small intestine was closed transversely, and an incidental appendectomy was performed. The patient was discharged on the 6th postoperative day. Histologically, the polypoid mass consisted of well-differentiated gastric mucosa with many parietal cells within the mucosal glands. In this patient, mesenteric lymphadenopathy and recent respiratory infection may have accelerated intestinal peristalis, and disposed to intestinal intussusception.

6142 EFFECT OF LOW-RESIDUE FOOD ON INDOMETHACIN-INDUCED INTESTINAL LESIONS IN RATS. *(E.)* Drees, D. T.; Robbins, T. L.; Crago, F. L. (Warren-Teed Pharmaceuticals Inc., Columbus, Ohio). *Toxicol. Appl. Pharmacol.* 27(1):194-199,1974.

To show whether prevention of indomethacin-induced gastrointestinal irritation and ulceration by food deprevation on the day of administration of the drug might be related to the avoidance of nondigestible residual components in the diet, experiments were carried out on the effect of administration of indomethacin to Sprague-Dawley rats on low residue (W-T Low Residue Food) and high residue (Purina Laboratory Chow) diets. In rats fed Purina Laboratory Chow, a single large dose of indomethacin (16 mg/kg) produced intestinal perforations in 100% of the animals and adhesions within 72 hr. When the laboratory chow was replaced with W-T Low Residue Food, no intestinal perforations or adhesions were observed. Feeding low-residue food only on the day indomethacin was administered prevented adhesions and perforations. In contrast, laboratory chow fed only on the day the drug was administered resulted in 100% incidence of intestinal lesions. The addition of increasing amounts of cellulose or laboratory chow to low-residue foods resulted in increasing amounts of fecal residue and a corresponding increase in intestinal ulcer incidence and severity. These results indicate that low-residue diets can significantly decrease the toxicity of indomethacin in rats and that their possible use for reducing gastrointestinal side effects caused by indomethacin and other anti-inflammatory agents in man warrants further investigation.

6143 NON-NEUROGENIC INTESTINAL TUMORS IN VON RECKLINGHAUSEN'S DISEASE. *(Sp.)* Rivas Rodero, S.; Ramos Freixa, J. (La Fe Munic. Sanit., Valencia, Spain). *Rev. Esp. Enferm Apar. Dig.* 43(1): 69-74, 1974.

Case reports are presented for a 2-yr-old boy and a 1-yr-old girl with cutaneous neurofibromatosis who had multiple leiomyomas in the duodenum and jejunum, resp. In addition, the girl had an adenomatous polyp of the stomach. Both patients presented with gastrointestinal bleeding. The association between von Recklinghausen's disease and leiomyomas of the small intestine is difficult to explain if neurofibromatosis is considered to be only a neuroectodermal anomaly. It is suggested that this condition involves both the neural ectoderm and mesoderm which would account for the development of tumors and dysplasia in a great variety of organs and tissues. It is recommended that staining with Masson's trichrome or alcian blue be used to distinguish between neurofibromas and leiomyomas and that phosphotungsticacid-hematoxylin be used to demonstrate the existence of myofibrils in the cytoplasm. Silver impregnation methods are also useful since they show reticulin fibers encircling the cells in leiomyomas.

6144 CONGESTIVE AND HEMORRHAGIC LESIONS OF THE DUODENUM: ENDOSCOPIC AND BIOPSY FINDINGS. *(Fr.)* Cheli, R.; Aste, H.; Ciancamerla, G. (San Martina Hosp., Genoa, Italy). *Arch. Fr. Mal. App. Dig.* 63(2):109-113, 1974.

After premedication with meperidine hydrochloride (100 mg), promethazine hydrochloride (50 mg), and atropine (0.5 mg) and local anesthesia with lidocaine, endoscopic examinations of the duodenum were performed with an Olympus GIF esophagogastroduodenoscope and 3 biopsies were removed from each of 29 patients, aged 20-68 yr. To rule out the possibility of trauma, none of these patients had dyskinesia of the antrum, pylorus, or duodenum which might cause or favor retrograde intussusception at duodenoscopy and no aspiration was performed. None of the patients had any diseases which would favor bleeding (alcoholism, liver disease, or hemorrhagic disorders) and none had recently taken any medication known to cause gastrointestinal bleeding. These patients presented with painful dyspepsia (13 cases), hyposthenic dyspepsia (13 cases), and dyspepsia associated with cholelithiasis (3 cases). Radiological examination showed no significant changes in the duodenum. Duodenoscopy revealed disseminated petechiae and ecchymoses in the anterior and posterior mucosa of the duodenal bulb in 5 cases. In 2 of these patients the lesions extended into the 2nd part of the duodenum, and in 2 other patients they were limited to the 2nd part of the duodenum. Areas of congestion were present in 11 patients. These lesions were limited to the bulb in 6 cases, to the 2nd part of the duodenum in 2 cases, and were present in the 1st and 2nd parts of the duodenum in 2 cases. In 9 cases congestion was associated with petechiae and ecchymoses. These lesions were located in the bulb (4 cases) or in the 1st and 2nd parts of the duodenum (5 cases). Histological examination of biopsied material showed the presence of congestion in all cases associated with hemorrhagic extravasation which was particularly evident in the villi. Hemorrhagic infiltration was occasionally associated with microerosions in the epithelium of the villi. Vascular congestion of the muscularis mucosae was not observed as frequently. Although small leukocyte infiltrates were present, only 2 patients had superficial duodenitis. It is concluded that these congestive and hemorrhagic lesions of the duodenum result from vascular disorders rather than inflammation.

SMALL INTESTINE

Malabsorption

6173 ^{15}N STUDIES OF ENDOGENOUS FAECAL NITROGEN IN INFANTS. *(E.)* Read, W. W. C.; McLaren, D. S.; Tchalian, M. (Sch. Med., American Univ. Beirut, Lebanon). *Gut* 15(1):29-33, 1974.

In this study of nitrogen absorption, fecal nitrogen was analyzed as to its source, whether directly from the diet or endogenous. Four male Arab infants (3-12 months old) suffering from acute and severe energy-protein malnutrition of the marasmic type or fully recovered from the condition were tested. Before the first meal of the day, ^{15}N-yeast protein (0.7 mg ^{15}N/kg) was administered by stomach tube. Carmine, mixed with the first meal after such administration, acted as a stool marker. All stool samples, passed shortly after the labelled protein was given and up to 100 hr thereafter, contained measurable amounts of ^{15}N, only a part of which was from an unabsorbed source as shown by the presence of carmine. No difference in the mean excretion of total ^{15}N (0.4% of dose) in carmine-marked stools was apparent between marasmic and recovered subjects. In the 2nd part of this study, 3 other infants, 2 marasmic and 1 recovered, received i.v. ^{15}N-urea (1 mg ^{15}N/kg); and nitrogen from this source appeared in all stools passed during the 72 hr experimental period. In general, these findings show that labelled nitrogen is incorporated into the feces by 3 different routes: (1) in water-soluble materials, products of absorption and metabolism of the test substances; (2) unabsorbed materials; and (3) in water-insoluble materials, primarily components of bacterial and sloughed-off intestinal cells, which are the 2 main types of cells present in stools. It is suggested that bacteria may be a site of amino acid synthesis. Some of these bacterially-synthesized amino acids might be released into the intestinal lumen, and thereby act as an auxiliary supply of essential and nonessential amino acids during starvation.

6174 INTESTINAL LYMPHANGIECTASIA: REPORT OF A CASE WITH ASYMMETRICAL JAUNDICE. *(E.)* Garcia-Alvarez, J.; Reverte-Cejudo, D.; Bernaldo-De-Quiros-Gonzalez, J.; Valle-Jimenez, A. (Clin. Hosp., Univ. Complutense, Madrid, Spain). *Digestion* 10(1):73-81, 1974.

A 22-yr-old man exhibited chronic diarrhea, assymmetrical edema, and hypoproteinemia. Both the diarrhea and asymmetrical edema had been present since childhood. The protein intake was normal, no evidence of liver failure was found, and the urine contained no protein. The assumption that the gastrointestinal tract was responsible for the hypoproteinemia was confirmed by the ^{131}I-polyvinylpyrrolidone test, which indicated the presence of a protein-losing enteropathy. A histopathological study of the small bowel showed extremely dilated lacteals. This finding, together with the asymmetrical edema and onset in childhood, demonstrated the presence of intestinal lymphangiectasia. A mechanical explanation for the loss of substances into the gut lumen was suggested by the occurrence of endothelial gaps and of amorphous material with lipid droplets at both sides of the endothelial walls of the lacteals. Except for a slightly abnormal D-xylose test, this case is an almost typical example of primary intestinal lymphangiectasia. During his hospitalization, the patient developed acute viral hepatitis, evidenced by jaundice, enlargement and tenderness of the liver, SGOT 1300 U, and SGPT 1260 U. All signs returned to normal after 1 month, but the jaundice took more time to disappear on the left side of the body. Two asymmetric skin biopsies, taken from both forearms, showed no abnormality or asymmetry of the lymph vessels.

6175 PLASMA POST-HEPARIN LIPOLYTIC ACTIVITY IN PATIENTS WITH MALABSORPTION: EFFECT OF INTRAVENOUS FAT ADMINISTRATION. *(E.)* Press, M.; Thompson, G. R. (Hammersmith Hosp., London, England *Clin. Sci. Mol. Med.* 46(6):743-751, 1974.

Plasma lipolytic activity was determined in 13 patients with malabsorption and 14 healthy controls. Before measurements were made, the test subjects were fasted overnight and, 10 min before withdrawal of venous blood, 0.1 mg/kg heparin was injected via an antecubital vein to promote release of lipolytic activity into the circulation. Three different substrates were used: very low-density lipoprotein (VLDL), prepared from normal fasting plasma within 24 hr of use, and 2 artificial substrates, i.e. a coconut oil emulsion and triolein. Lower post-heparin lipolytic activities were found in malabsorbers, no matter which substrate was used, but activities rose in malabsorbers after therapeutic doses of an i.v. fat emulsion (Intralipid), especially when VLDL was used as the substrate. The lipolysis shown by sera of both malabsorbers and controls was inhibited by 0.5 M sodium chloride when VLDL was the substrate but not when the 2 artificial substrates were used. This indicated that post-heparin lipolytic activity is heterogenous in origin and was consistent with the concept that post-heparin lipolytic activity, measured with artificial triglyceride substrates, largely reflects liver triglyceride lipase, while activity measured with VLDL reflects adipose tissue lipase.

6176 BACTERIAL PATHOGENESIS OF STEATORRHEA IN GASTRECTOMIZED PATIENTS: STUDY OF JEJUNAL BACTERIA CAPABLE OF DECONJUGATING BILE SALTS.

(It.) Sammarro, L.; Ferri, S. (Inst. Clin. Gen. Med. Med. Therap., Univ, Bologna, Italy). *Arch. Ital. Mal. App. Dig.* 37(2):91-101, 1973

Microbiological studies were performed on jejunal aspirates from 15 patients (12 men and 3 women, aged 31-63 yr) who had undergone Billroth II gastroenterostomy for duodenal ulcer more than 6 months previously. All patients were more than 10% below their ideal weight and all but 3 had steatorrhea. No bacteria were isolated in jejunal aspirates from 3 patients, while 3 or 4 species were found in each of the aspirates from the remaining 12 patients. The most common species was *Escherichia coli* (11 cases) followed by *Proteus* (7), *Streptococcus faecalis* (6), *Staphylococcus* (5), and *Strep. haemolyticus* (4) and *viridans* (2). *Candida* was isolated in 4 cases, but no anaerobic bacteria were detected. Quantitatively normal flora were present in only 1 patient (fewer than 10^4 colonies/ml aspirate). *E. coli* was present in larger numbers (10^6 colonies/ml aspirate) than *Strep. faecalis* (10^3 colonies/ml aspirates). With the exception of *Strep. faecalis,* none of these organisms is capable of deconjugating bile salts. It is suggested that steatorrhea in these patients is probably due to changes in motility, gastrointestinal insufficiency, and mucosal atrophy, rather than to deconjugation of bile salts by the intestinal flora.

6177 JEJUNAL MUCOSAL IMMUNOGLOBULIN-CONTAINING CELLS AND JEJUNAL FLUID IMMUNOGLOBULINS IN ADULT COELIAC DISEASE AND DERMATITIS HERPETIFORMIS.

(E.) Lancaster-Smith, M.; Kumar, P.; Marks, R.; Clark, M. L.; Dawson, A. M. (St. Bartholomew's Hosp., London, England). *Gut* 15(5):371-376, 1974.

Densities of immunoglobulin-containing plasma cells in the jejunal mucosa and serum, and jejunal fluid immunoglobulins, were measured in 14 patients with adult celiac disease and 14 with dermatitis herpetiformis with and without jejunal mucosal abnormality. There were 14 controls. Studies were performed in patients before and after treatment of the jejunal lesion with a gluten-free diet. Total immunofluorescent plasma cells were increased in untreated adult celiac disease and dermatitis herpetiformis patients with jejunal lesions, but in general the normal predominance of IgA>IgM>IgG was found. There was no difference from controls in IgA-containing cells in the two conditions before or after treatment. The numbers of IgM-containing cells were significantly increased both before and after treatment in groups of patients with adult celiac disease and dermatitis herpetiformis who had jejunal lesions. IgG-containing cells were significantly raised in only the before-treatment groups. Patients with dermatitis herpetiformis without jejunal lesions, even while on gluten-containing diets, had normal numbers of immunoglobulin-containing cells. IgA and IgM jejunal fluid immunoglobulins were significantly raised in dermatitis herpetiformis and adult celiac disease. It is concluded that patients with dermatitis herpetiformis with jejunal morphological abnormality have an immunological disturbance of the jejunal mucosa comparable to that found in adult celiac disease.

6178 FAT ABSORPTION AFTER INFUSING BILE SALTS INTO THE HUMAN SMALL INTESTINE. *(E.)*

Shimoda, S. S.; O'Brien, T. K.; Saunders, D. R. (Univ. Washington Sch. Med., Seattle). *Gastroenterology* 67(1):7-18, 1974.

Absorptive cell abnormalities during fat absorption have recently been demonstrated by electron microscopy in some patients with small intestinal stasis syndrome. Whether deconjugated bile salts, produced by jejunal bacteria, might cause these abnormalities was tested by feeding an intragastric liquid test meal (egg lipids, linseed oil, and phenol red marker) to 3 normal volunteers after prior overnight infusion with conjugated or unconjugated bile salts or with bicarbonate-buffered saline. No definite morphological evidence of injury to jejunal absorptive cells was discerned after infusing 1 or 2 mM deoxycholate. In biopsy sections, the only consistent difference was seen after overnight infusion of deoxycholate, i.e., a marked decrease in the numbers of fat particles in the apical areas of absorptive cells located 10-20 cells below the villus tip. This finding was not seen after overnight infusion of conjugated bile salts or buffered saline, or after no overnight infusion. A marked decrease in apical fat particles was also observed in 3 patients with stasis syndrome after overnight deoxycholate infusing. The abnormality may be explained by an inhibitory effect of unconjugated bile salts on reesterification of free fatty acids by the jejunal mucosa.

6179 THE CELL POPULATION OF THE UPPER JEJUNAL MUCOSA IN TROPICAL SPRUE AND POSTINFECTIVE MALABSORPTION.

(E.) Montgomery, R. D.; Shearer, A. C. I. (East Birmingham Hosp., England). *Gut* 15(5):387-391, 1974.

The lymphocyte and plasma cell population in jejunal biopsy specimens from 12 patients with tropical sprue acquired in Southeast Asia or the Middle East was compared with that in 9 cases of post-infective malabsorption arising in Western Europe and with 12 cases of untreated celiac disease. Infiltration of the epithelial layer of the upper jejunal mucosa by lymphocytes was found in tropical sprue to the same extent as in celiac disease and, to a lesser extent, in postinfective malabsorption. In all forms of acute sprue, there was increased density of lymphocytes in the lamina propria. With increasing duration and with increasing mucosal atrophy, the lymphocytes were progressively replaced by plasma cells; and the cellular infiltration in chronic sprue was indistinguishable from that of celiac disease. The findings suggest that a humoral antibody response is a feature of sprue and that this becomes more prominent as the condition becomes chronic.

6180 CELLULAR INFILTRATE OF JEJUNAL BIOPSIES IN ADULT COELIAC DISEASE IN RELATION TO GLUTEN WITHDRAWAL. *(E.)* Holmes, G. K. T.; Asquith, P.; Stokes, P. L.; Cooke, W. T. (Dept. Exp. Pathol., Univ. Birmingham, England). *Gut* 15(4):278-283, 1974.

Inflammatory cell counts in the lamina propria and epithelium of jejunal biopsies in 11 patients with adult celiac disease were compared with counts found in 12 controls with no evidence of bowel disease. In the patients with celiac disease, there were significant increases in the number of total cells, plasma cells, and intraepithelial lymphocytes but a significant reduction in lamina propria lymphocytes. Following clinical improvement on a strict gluten-free diet for up to 9 yr, cell counts changed significantly but, with the exception of lymphocytes in the lamina propria, were still abnormal. Analysis of 5 patients in whom the biopsy improved to near normal morphology and of 6 showing no such improvement revealed significantly higher plasma cell counts in the latter but no significant differences between groups for other counts. On the basis of the observed changes in cell counts, there appears little justification for questioning the diagnosis of celiac disease in patients who show unequivocal clinical response to gluten withdrawal but no gross morphological improvement in the jejunal biopsy. It is suggested that local antigenic stimulus with gluten transforms lymphocytes in the lamina propria to plasma cells, while removal of gluten from the diet results in reaccumulation of lymphocytes and a decrease in plasma cells. Persistence of abnormal cell counts in the mucosa after gluten withdrawal suggests that patients continue to ingest enough gluten to stimulate the immune system without producing clinical deterioration or gross morphological abnormalities. Alternatively, the mucosa could be so severely damaged by long exposure to gluten that the normal microstructure cannot be restored after gluten withdrawal.

6181 CHRONIC SKIN DISEASE AND INTESTINAL ABSORPTION: BIOPSY AND FUNCTIONAL STUDY OF THE SMALL INTESTINE IN 35 CASES. *(Fr.)* Matuchansky, C.; Certin, M.; Bognel, J. C.; Bognel, C.; Modigliani, R.; Daniel, F.; Galian, A.; Civatte, J.; Bernier, J. J. (St. Lazare Hosp., Paris, France). *Ann. Med. Interne (Paris)* 125(3):253-259, 1974.

Histological examination of staged ileal and jejunal biopsies and biological tests for malabsorption were performed on 35 patients with untreated chronic skin diseases (group A), and skin and mucosal lesions were systematically investigated in 110 patients who presented with biologically confirmed malabsorption (group B). Patients in group A consisted of 10 with eczema, 15 with psoriasis, 5 with dermatitis herpetiformis, and 5 with miscellaneous skin diseases. Except for 8 patients with watery diarrhea and normal fat excretion, none of these patients had clinical manifestations of malabsorption. Only 2 patients (1 with eczema and 1 with dermatitis herpetiformis) had subtotal villous atrophy, and 5 of the 10 eczema patients had partial villous atrophy. Biological tests revealed that 2 patients with psoriasis had pancreatic insufficiency, steatorrhea, and creatorrhea associated, in 1 case, with microbial overgrowth of the proximal small intestine; 3 other patients had only moderate creatorrhea. In addition to 6 patients with a hyperglycemic response to p.o. lactose loading, 9 had only one abnormal absorption test each. Only 3 patients (2 with psoriasis and 1 with dermatitis herpetiformis) had 2 or 3 abnormal tests (folic acid, vitamin B_{12}, or glucose absorption). No correlation was found between results of absorption tests and histological findings. Strictly normal absorption tests were obtained from 3 of the 5 patients with eczema and partial villous atrophy; the other 2 patients had only 1 abnormal test each (hyperglycemic response to glucose and the Schilling test, resp.). Of 110 patients in group B, only 10 (9%) had skin diseases. The incidence of skin disease in this group was only slightly higher than that in a control group of hospitalized patients. With the exception of a patient with intestinal Hodgkin's disease and general ichthyosis, the skin lesion was never indicative of malabsorption.

6182 COLLAGENOUS SPRUE. *(E.)* Pepper, H. W.; Brandborg, L. L.; Shanser, J. D.; Goldberg, H. I.; Moss, A. A. (Univ. California Sch. Med., San Francisco). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 121(2):275-282, 1974.

The cause of collagenous sprue is as yet undetermined. Patients with clinical malabsorption, histogically flat mucosa of the jejunum and little or no response to gluten withdrawal are prime suspects. In 3 cases investigated here, jejunal biopsy specimens showed flat mucosa with an abundant deposit of collagen lying beneath the surface epithelium and extending into the lamina propria. Serial and multiple biopsy specimens were required to make the diagnosis, and Trichrome staining was essential. Roentgenograms revealed moderate to severe changes in the proximal small bowel differing somewhat from the characteristic appearance of celiac sprue. Duodenal involvement was present in each of the 3 cases and varied from mucosal thickening of the proximal small bowel to a virtually smooth, featureless rigid pattern. Such features in patients with primary intestinal malabsorption that is partially or totally refractory to strict exclusion of gluten from the diet should alert the radiologist to the possible presence of collagenous sprue. Differentiation of collagenous sprue from celiac sprue allows for a more accurate prognosis and a more definitive treatment for the patient.

6183 DERMATITIS HERPETIFORMIS: IMMUNOLOGIC CONCOMITANTS OF SMALL INTESTINAL DISEASE AND RELATIONSHIP TO HISTOCOMPATIBILITY ANTIGEN HL-A8. *(E.)* Gebhard, R. L.; Falchuk, Z. M.; Katz, S. I.; Sessoms, C.; Rogentine, G. N.; Strober, W. (Natl. Inst. Arthritis, Metabol., Digest. Dis., Bethesda, Md.). *J. Clin. Invest.* 54(1):98-103, 1974.

The relation between the gluten-sensitive intestinal lesion observed in dermatitis herpetiformis and in gluten-sensitive enteropathy was analyzed. Jejunal IgA synthesis in dermatitis herpetiformis was estimated from the extent of incorporation of ^{14}C-leucine into IgA in jejunal biopsy specimens during short-term *in vitro* culture. Dermatitis herpetiformis patients have significantly elevated incorporation values as compared to normal controls, 18,000 vs 5,830 cpm/mg tissue protein/90 min, and the degree of elevation correlated well with the degree of morphologic abnormality. Thus dermatitis herpetiformis patients are similar to gluten-sensitive enteropathy patients where elevated local mucosal IgA synthesis has also been observed. Of the 8 patients with dermatitis herpetiformis and intestinal disease, 7 carried the histocompatibility antigen HL-A8 (87.5%). Of the 7 patients with dermatitis herpetiformis without intestinal disease, 2 had HL-A8 (27%), an incidence not significantly different from that of the general population (20%). Thus the intestinal lesion of dermatitis herpetiformis is similar to that of gluten-sensitive enteropathy, both in respect to local mucosal increase in IgA synthetic rates and in respect to the association with HL-A8.

6184 MALABSORPTION OF FOLIC ACID FOLLOWING PARTIAL GASTRECTOMY. *(E.)* Elsborg, L. (Univ. Dept. Med., Arhus, Denmark). *Scand. J. Gastroenterol.* 9(3):271-274, 1974.

Malabsorption of folic acid was detected by the tritiated folic acid absorption test in 14 of 40 patients (21 men and 19 women, average age 57 yr) who had undergone gastrectomy for benign gastric or duodenal ulcers. The procedures employed were Polya gastrectomy with resection of more than 1/3 of the stomach (29 patients), antrectomy with less extensive resection (4 patients), and the Billroth I operation (3 patients). Apart from gastrectomy, none of these patients had other gastro-intestinal or metabolic diseases which might interfere with folate metabolism. Folate deficiency, defined as serum folate levels below 2.0 ng/ml, was present in 6 patients with reduced folic acid absorption; 5 of these patients also had low whole-blood folate concentrations and 3 had increased urinary formiminoglutamic acid. Overt anemia was present in 1 patient with a megaloblastic bone marrow. In the remaining 8 patients with folic acid malabsorption, serum and whole-blood folate concentrations were normal. The true incidence of folic acid malabsorption in postgastrectomy patients is probably lower than that found in this group since these patients had severe complaints after surgery. It is suggested that folate deficiency in postgastrectomy patients may occasionally originate from malabsorption of dietary folic acid. In some gastrectomized patients, the synthesis of folate by microorganisms in the small intestine apparently compensates for decreased folic acid absorption.

6185 SELECTIVE MALABSORPTION OF VITAMIN B_{12}: REPORT OF A CASE WITH METABOLIC STUDIES. *(E.)* Rubin, H. M.; Giorgio, A. J.; Macdonald, R. R.; Linarelli, L. G. (Mercy Hosp., Pittsburgh, Pa.). *Am. J. Dis. Child.* 127(5):713-717, 1974.

A 9-yr-old boy with selective malabsorption of vitamin B_{12} had megaloblastic anemia, proteinuria, failure to absorb orally administered radioactive vitamin B_{12}, low serum B_{12} level, increased excretion of methylmalonic acid, and absence of intrinsic factor antibodies. The anemia and methylmalonic acid excretion responded quickly to parenteral vitamin B_{12} (1 mg) therapy, but a generalized aminoaciduria persisted. Sufficient therapy was documented by inability to increase urinary methylmalonic acid excretion with an oral DL-valine load. Elevated excretion or clearance of threonine, alanine, tyrosine, histidine, glycine, serine, and leucine was present before and after therapy, supporting the concept of an associated distinct renal tubular defect separate from vitamin B_{12} dependent metabolic pathways. Selective malabsorption of vitamin B_{12} is a rare cause of vitamin B_{12} deficiency in children but should be suspected when megaloblastic anemia is accompanied by proteinuria. Studies such as intrinsic factor antibodies, gastric biopsies, Schilling stages, and mode of inheritance may be necessary to distinguish selective malabsorption of vitamin B_{12} from other vitamin B_{12} deficiency states.

6186 STUDY OF IMMUNOGLOBULIN-CONTAINING CELLS IN THE INTESTINAL MUCOSA OF NORMAL SUBJECTS AND PATIENTS WITH CELIAC DISEASE. *(Sp.)* Serra Desfilis, M. A.; Gasbarrini, G.; Miglio, F.; Rodrigo Gomez, J. M.; Aparisi Quereda, L.; Guix Garcia, J.; Garcia-Conde Gomez, F. J. (Fac. Med., Valencia, Spain). *Rev. Esp. Enferm. Apar. Dig.* 42(3):323-334, 1974.

Biopsies were obtained from the small intestine, 20 cm from the level of the angle of Trietz, from 8 pateints (aged 26-66 yr) with celiac disease who had been treated with a gluten-free diet for 6 months to 3 yr. Twelve subjects (aged 24-56 yr) with no evidence of gastrointestinal or immunological disease served as controls. Examination of the biopsies with immunofluorescence technique showed that the mean densities of IgG- and IgM-type cells were significantly greater in patients with celiac disease, but the densities of IgA-type cells did not differ significantly between patients and controls. It has been suggested that increases in the density of IgM-type cells in celiac disease might be a manifestation of antigen-antibody complex formation. These complexes could secondarily fix complement and produce the lesions of celiac disease. The increase in IgG-type cell density is considered to be a nonspecific finding for which there is no logical explanation.

6187 SELECTIVE MALABSORPTION OF VITAMIN B_{12}: REPORT OF A CASE AND STUDIES OF VITAMIN B_{12} ABSORPTION. *(E.)* Koide, R.; Kikuchi, K.; Tsunematsu, Y. (Natl. Child. Hosp., Tokyo, Japan). *Keio J. Med.* 22(1):45-57, 1973.

A boy aged 2 yr and 10 months who was born of consanguineous parents presented with megaloblastic anemia. The patient excreted 123 mg/day methylmalonic acid, which increased to 268 mg/day on loading with L-valine, a precursor of methylmalonyl coenzyme A. Abnormal excretion of methylmalonic acid has been reported in some cases of vitamin B_{12} deficiency; moreover, vitamin B_{12} acts as a coenzyme of isomerase in the pathway from methylmalonyl coenzyme A to succinyl coenzyme A. The conclusion that the megaloblastic anemia was due to vitamin B_{12} deficiency was supported by the striking response to treatment with vitamin B_{12} (1000 μg i.m.). The urinary methylmalonic acid level returned to normal (4 mg/day), while a remarkable reticulocytosis was apparent within one day of treatment and a marked increase in hemoglobin within 4 days. As the Schilling test was performed 5 times over the 4-month treatment period, the patient received 5 i.m. injections of 1000 μg vitamin B_{12}. Anemia disappeared after the 1st dose of vitamin, and both platelet and leukocyte counts returned to normal. The Schilling test indicated that vitamin B_{12} malabsorption was present throughout the anemic and convalescent stages. Addition of intrinsic factor did not increase urinary ^{57}Co-vitamin B_{12}, indicating the absence of pernicious anemia. Other tests revealed no obvious morphological abnormality in the intestinal tract, no significant utilization of vitamin B_{12} by intestinal flora, or chronic pancreatitis. Because his parents were consanguineous and he had benign proteinuria (13-85 mg/dl), it was concluded that the child had selective vitamin B_{12} malabsorption caused by a congenital, functional absorption abnormality in the mucosa of the small intestine. The patient continues to receive p.o. vitamin B_{12} (250 μ/day) and after 20 months maintains a completely normal blood picture.

LARGE INTESTINE

6203 PATHOLOGY OF COLONIC POLYPS AS IT RELATES TO SURGICAL MANAGEMENT. *(E.)* Enterline, H. T. (Hosp. Univ. Pennsylvania, Philadelphia) *Ann. Clin. Lab. Sci.* 4(3):145,150, 1974.

Polypoid tumors of the colon under 1 cm may be treated conservatively. Of the adenomatous types, large sessile adenomas, villous or otherwise, are best handled by segmental resection or by complete excision followed later by radical surgery if further pathologic examinations indicate this is necessary. The presence of a pedicle is no guarantee of the absence of carcinoma. Although metastases have been reported with carcinoma confined to the head of the stalk polyps, this is so rare that conservative surgery is adequate if the base is clear. This is also true of stalked polyps that appear to be entirely carcinomatous. Lymph node metastases appear to be confined to those adenomas containing sizable areas of carcinoma and which show invasion at least to the depth of the muscle coat. Lymph node metastases from pure carcinomas are not seen except for those in which invasion has occurred to at least the level of the muscle coat. Mixed villous and adenomatous polyps are very common and most polyps larger than 1.5 cm are of mixed type. There appears to be a correlation between the presence of both *in situ* and invasive carcinoma with villoglandular elements. In a series of 174 pure adenomas, only 7% contained *in situ* carcinoma and 1 case, an invasive carcinoma. In 80 mixed villous and glandular adenomas, however, 18.7% contained *in situ* carcinoma and 3 cases, an invasive carcinoma. Biopsies of polypoid lesions of the colon are preferably excisional. In the patient in whom excision is difficult, polyps of estimated size of 1 cm or less can probably be safely followed rather than excised. They should not be ignored since growth and subsequent carcinoma may occur. Since these are high risk populations in which about 20% of the patients will have a frank carcinoma somewhere in the colon, careful examinations of the colon should be performed at short intervals.

6204 PNEUMATOSIS INTESTINALIS. *(E.)* Heideman, M.; Darle, N.; Nilsson, A. E. (Sahlgrenska Hosp., Goteborg, Sweden). *Acta Chir. Scand.* 140(2): 164-166, 1974.

Case reports are presented for 2 men (aged 87 and 67 yr) with pneumatosis intestinalis. Both patients presented with meteorism and the older man also had vague abdominal distress and fever. In the latter case, review of x-ray films taken 3 yr previously showed an accumulation of gas-filled cysts in the wall of the signoid colon, while a barium enema study on admission revealed a partial obstruction between the sigmoid and rectum. The obstruction was apparently due to coarse folds of the mucosa. After the patient's sudden death, autopsy revealed fresh cerebral malacia and diffuse peritonitis. Although volvulus was not seen, it is possible that the changes in the mucous lining of the intestine were due to an early attack of volvulus and that the peritonitis was secondary to a perforation of a ruptured gas cyst. The 2nd patient was without clinical evidence of perforation, but free gas in the abdomen was seen on x-rays and was found, along with submucosal cysts, at laparotomy. The patient was discharged after 9 days but died 1 1/2 yr later of a subarachnoid hemorrhage. This case indicates that free gas in the abdomen could mean pneumatosis intestinalis, rather than rupture of gasholding viscus.

6205 POSTOPERATIVE PARENTERAL HYPERALIMENTATION AND WOUND HEALING IN ONCOLOGICAL SURGERY. *(It.)* Bozzetti, F.; Terno, G.; Longoni, C. (Natl. Inst. Tumor Res. Ther., Milan, Italy). *Tumori* 60(1): 53-63, 1974.

Only parenteral solutions were administered to 8 patients who had rectal adenocarcinomas for the first 5 days after amputation of the rectum. These solutions contained amino acids and dextrose with smaller quantities of levulose, sorbitol, and ethyl alcohol. Four patients (2 men and 2 women, mean age 57 yr) received a formula containing 12.4 cal/kg/day and 0.044 g N/kg/day (group 1) while the other 4 (3 men and 1 woman, mean age 59 yr) received 52.7 cal/kg/day and 0.235 g N/kg/day (group 2, hyperalimentation). The mean weight of patients given hyperalimentation was lower (52 kg) than those given the other formula (71 kg), but no other criteria were adopted in the selection of therapy. Patients in group (2) also received more than 100 mEq/day potassium, insulin (mean dose of 100 IU/day, and norandrostenolone decanoate (25 mg i.m.) on the first postoperative day. While patients in group (1) were infused for only 12 hr/day, catheters were placed in the subclavian veins of patients in group (2) and they were infused almost continuously for 5 days. Determinations of total nitrogen in 24-hr urine specimens showed that the nitrogen balance was negative in group (1) and positive in group (2). Collagen synthesis was investigated by chromatographic determination of hydroxylysine in biopsies taken from the wounds of these patients 2-15 days after surgery. Mean hydroxylysine contents were 0.013 mg/100 mg tissue for group (1) and 0.0250 mg/100 mg tissue for group (2), suggesting that hyperalimentation may promote wound healing. The postoperative course was similar in all patients. Among patients in group (2) no metabolic disorders associated with hyperalimentation or complications caused by catheterization of the subclavian vein were observed.

6206 PATHOLOGY OF INTESTINAL POLYPS: A HISTOLOGICAL COMPARISON OF ADENOMAS IN AUTOPSY AND SURGICAL MATERIAL. *(Jap.)* Sato, E.; Ouchi, A. (Med. Sch., Tohoku Univ., Sendai, Japan). *Jap. J. Cancer Clin.* 19(12):1159-1167, 1973.

To confirm the basic relation between cancer and polyps of the large intestine, pathological investigations were made of material from 1000 autopsied patients and 122 patients who underwent surgery. In autopsied patients the incidence of adenoma was 9.5% (10% in males and 8.8% in females). Hypertrophic mucosal tags occurred in 3.5%, juvenile polyps in 0.3%, Peutz-Jeghers polyps in 0.2%, and hyperplastic (metaplastic) polyps in 1.1%. The incidence of adenomas increased with advancing age. Of the adenomas, 55.1% were found in the right colon, 25.4% in the left colon, and 19.5% in the sigmoid and rectum. Histological examinations revealed that atypia was more pronounced in adenomas in the distal part of the large intestine than in those in the proximal part. Atypia was more pronounced in material from operated patients than in that from autopsy cases.

6207 RADIATION-INDUCED CARCINOMA OF THE RECTUM. A LATE COMPLICATION OF PELVIC IRRADIATION. *(E.)* Qizilbash, A. H. (Henderson Gen. Hosp., Hamilton, Canada). *Arch. Pathol.* 98(2): 118-121, 1974.

Adenocarcinoma of the rectum developed in a 61-yr old woman 24 yr after she received pelvic irradiation (1600 r deep x-ray therapy and 5865 mg/hr radium) for squamous cell carcinoma of the cervix. The resected bowel showed evidence of radiation changes with ulceration and stricture formation, the latter first observed 9 yr after irradiation. A well-differentiated papillary carcinoma had developed at the margins of the ulcer with infiltration into the muscle coat of the rectum. The bowel wall at this site was severely sclerosed with fibrosis of the submucosa and the muscular layer. In addition, arteries within the wall of the rectum showed typical radiation changes such as hyalinization with disruption of elastic fibers. No regional lymph node involvement was demonstrated, and the patient remains alive and well 6 1/2 yr after surgery. This case indicated the need for careful follow-up studies on patients with radiation-induced proctocolitis. Any ulcerated or suspicious lesions should be biopsied to rule out development of a carcinoma.

6208 NON-INVASIVE COLONOSCOPIC POLYPECTOMY. *(E.)* Panish, J. F.; Berci, G. (Cedars Lebanon Hosp., Los Angeles, Calif.). *West. J. Med.* 121(1): 6-9, 1974.

During 111 colonoscopies on 100 consecutive patients (68 men and 32 women, aged 36-88 yr), 183 polyps were removed by electrosurgery. Polypectomies were performed on patients who had polypoid lesions in the colon measuring more than 1 cm in diameter on barium enema, and any polypoid lesion was removed, regardless of size if there was a history of family history of colonic polyps or carcinoma. Many small polyps were suctioned back through the colonoscope in fragmented form. Of the 35 polyps not recovered, all measured less than 1 cm in diameter and 2/3 (22) were under 0.5 cm. The majority of these small polyps were not detected with barium enema and were not the occasion for colonoscopy. The vast majority of polyps were benign adenomas. Seven adenomas and 1 villous adenoma showed carcinomatous changes. Resections were performed on 6 of these 8 patients, and no residual tumor was found in the pathological specimen in 4. Well-defined stalks were present on 2 of the 3 lipomas. Only 2 patients bled, and no perforations occurred in this series. Colonoscopic polypectomy costs less and entails less time in the hospital than laparotomy, colotomy and polypectomy.

6209 STUDIES OF HUMAN AMEBIASIS. II. LIGHT AND ELECTRON-MICROSCOPIC OBSERVATIONS OF COLONIC MUCOSA AND EXUDATE IN ACUTE AMEBIC COLITIS. *(E.)* Pittman, F. E.; El-Hashimi, W. K.; Pittman, J. C. (Med. Univ. South Carolina, Charleston). *Gastroenterology* 65(4):588-603, 1973.

Early amebic lesions in the sigmoid colon of 9 patients with unequivocal acute amebic colitis were studied in mucosal biopsy specimens and exudates. Material aspirated from all patients contained large numbers of motile hematophagous trophozoites of *Entamoeba histolytica* in a thick mucopurulent hemorrhagic exudate. In biopsies, a diffuse inflammatory process with or without superimposed focal ulceration was observed whether amebae were present in the tissue or not. Amebae were rarely found except at the superficial portions of the ulcers; even when present in large numbers at the surface ulcers, they were not seen deep in the mucosa or submcuosa. In addition, amebae were not found in the crypts of Lieberkuhn at any level, and were not observed penetrating intact epithelium or entering the lamina propria through microulcerations. Trophozoites were separated from viable tissue by a zone of necrotic material; interglandular surface epithelium appeared to be lysed prior to invasion by trophozoites. Ultrastructurally, microvilli were decreased in size, and number, mitochondria were swollen, vesicles of endoplasmic reticulum dilated, and the cytoplasms markedly vesiculated. In some areas, intracellular spaces were distended with edema fluid which appeared to escape into the lumen of the colon between surface epithelial cells. These findings suggest that the mucosal inflammatory process preceded focal epithelial ulceration and may be the result of toxic products released by amebae. Release of lysomal like vesicles from the surface membrane of amebae or rupture of amebae may be mechanisms by which toxic products are released.

6210 PERORAL KANAMYCIN PROPHYLAXIS IN COLON SURGERY. *(E.)* Gruner, O. P. N.; Ladehaug, B. (Ulleval Hosp., Oslo, Norway). *Acta Chir. Scand.* 140(2):156-158, 1974.

The effects of p.o. kanamycin and of postoperative chloramphenicol with penicillin were compared in 2 randomized groups of patients subjected to colon surgery. Administration of the kanamycin was begun 3 days before surgery, with an initial dose of 1 g given hourly 4 times and thereafter 1 g every 6 hours until the day of operation. Penicillin was administered twice at a dose of 1.5 million U, and chloramphenicol was given 4 times at a dose of 0.5 g/day, for 3 days after surgery. Use of kanamycin gave less favorable results, particularly with reference to suppuration, temperature above 39 C, need for additional antibiotics, more than 3 weeks hospital stay, and uneventful postoperative course. It was concluded that kanamycin prophylaxis was not beneficial and might be harmful.

Ulcerative Colitis

6239 CLINDAMYCIN (CLEOCIN) COLITIS. *(E.)* Cohen, L. E.; Smith, C. J.; Pister, J. D.; Wells, R. F. (Brooke Army Med. Ctr., Fort Sam Houston, Tex.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 121(2):301-304, 1974.

Clindamycin hydrochloride hydrate (150 mg 4 times/day p.o.), a synthetic antibiotic widely used against gram-positive and anaerobic organisms, caused severe protracted colitis in 6 patients. The main clinical feature was the sudden onset of severe diarrhea and abdominal pain mimicking inflammatory or vascular bowel disease. All patients required hospitalization despite cessation of clindamycin therapy. Barium enema examinations revealed that 3 patients had marked mucosal abnormalities. The abnormalities consisted of diffuse ulcerations, irregular mucosal masses, or uniform nodularity of the entire colon and rectum. An additional finding in 1 patient was the occurrence of toxic megacolon. These cases indicate that the roentgenographic findings of clindamycin colitis are nonspecific but suggestive of idiopathic ulcerative colitis, ischemic or infectious colitis, or Crohn's disease. Diagnosis of clindamycin colitis was established by the proctoscopic finding of unique cream-colored, plaque-like lesions superimposed on a friable or edematous mucosa. Biopsy of the plaque-like lesions revealed nonspecific inflammatory changes; no pathogens were obtained on culture. Treatment consisted of i.v. hydrocortisone, hydrocortisone enemas, and replacement of p.o. intake with i.v. fluids. This is the first detailed description of radiological findings in this type of colitis.

6240 AUTOLYMPHOCYTOTOXINS IN ULCERATIVE COLITIS AND CARCINOMA OF THE COLON. A LESION OF TOLERANCE. *(E.)* Sion, A.; Friedell, M. T. (Dept. Lab. Med., Jackson Park Hosp., Chicago, Ill.). *Int. Surg.* 59(3):141-146, 1974.

Serum from 16 patients with ulcerative colitis and 14 normal controls was tested for autolymphocytotoxicity. The reaction was of the cold type, maximal at 15 C, and was complement-dependent. This suggested that the antibodies were of a low affinity type or that the reaction was restricted to a limited number of immunodeterminants on the lymphocyte surface, accounting for the apparent elution at higher temperatures. Under the conditions used in the test, serum from 2 patients with adenocaranomas of the colon destroyed 65% of the target lymphocytes; that from 4 untreated patients, 55%; that from 3 patients with subtotal colectomy, 45%; and that from 7 prednisone-treated patients, about 10%, the same as that from normal controls. The blocking action of prednisone on the development of autolymphocytotoxicity in colitis patients was reversed after treatment was discontinued. It is hypothesized that carcinoembryonic antigen found in patients with malignant tumors of the colon and a modified type of secretory immunoglobulin A may have common immunodominant reactive surfaces recognized by the lymphocyte. This possibility is supported by previous reports of the occurrence of carcinoembryonic antigen in tumors arising from tissues secreting exocrine type immunoglobulin A and in patients with ulcerative colitis.

PANCREAS

6247 STUDIES OF GLUCAGON SECRETION IN PANCREATECTOMIZED PATIENTS. *(E.)* Muller, W. A.; Brennan, M. F.; Tan, M. H.; Aoki, T. T. (Peter Bent Brigham Hosp., Boston, Mass.). *Diabetes* 23(6):512-516, 1974.

Studies were conducted to determine if intestinal glucagon-like material that cross-reacts with antiglucagon antiserum is true glucagon derived from alpha cells in the intestinal tract. Arginine was infused (460 mg/kg i.v. over 40 min) in 2 totally pancreatectomized patients and 2 age- and sex-matched normal controls. Concentrations of plasma glucagon and of plasma glucagon-like immunoreactive (GLI) substances were determined with the aid of a relatively specific antiserum (30-K), an antiserum with intermediate specificity (02-K), and a nonspecific antiserum (78-J). Plasma glucagon levels, as measured with 30-K, did not increase in the pancreatectomized patients but increased 4-to 6-fold in controls. Assays of GLI with 02-K revealed similar differences. Assays of GLI with 78-J gave high, erratic results which lacked significance. Results of charcoal pretreatment of plasma indicated that interfering substances did not completely account for the basal level of total glucagon immunoreactivity measured in pancreatectomized patients with 30-K antiserum. The material in excess of the 20-30 pg/ml binding to charcoal is either true glucagon or represents substances cross reacting nonspecifically with the antiserum. If it represents a polypeptide identical to pancreatic glucagon, it originates in cells not responsive to arginine. If it represents nonspecific cross reactivity with 30-K, no glucagon antibody is entirely pancreatic-glucagon specific. The absence of plasma glucagon response to arginine in pancreatectomized patients suggests that extrapancreatic sites do not contain significant numbers of normally functioning alpha cells.

6248 COMPARATIVE DIAGNOSTIC VALUE OF ENDOSCOPIC PANCREATOGRAPHY AND PANCREATIC FUNCTION TESTS. *(E.)* Nakano, S.; Horiguchi, Y.; Takedo, T.; Suzuki, T.; Nakajima, S. (Ogaki Munic. Hosp., Japan). *Scand. J. Gastroenterol.* 9(4):383-389, 1974.

Endoscopic pancreatography, the pancreozymin-secretin test, urinary amylase determinations, and the glucose tolerance test were performed on 120 patients. Diagnosis consisted of cholelithiasis (15 cases), choledocholithiasis (12), chronic pancreatitis (21), carcinoma of the pancreas (7), and other diseases of the liver and duodenum (65). While abnormalities in pancreatograms were variable, 86% of the patients who had irregularity of the pancreatic duct had abnormal pancreozymin-secretin tests. The percentage of patients with irregularities of the pancreatic duct was best correlated with the degree of pancreatic dysfunction. In general, the incidence of pancreatic dysfunction increased as the diameter of the duct increased. Pancreatic dysfunction was found in about 35% of the patients who had normal pancreatograms. There were instances in which pancreatic function tests were of no value and an endoscopic pancreatogram was crucial for the diagnosis. Pancreatograms in patients with carcinoma of the pancreas were classified into 3 groups, and pancreatic function was evaluated. The characteristics of pancreas dysfunction shown by these types might be influenced by the location and size of the lesion. The obstruction type was advanced carcinoma; the carcinoma of the stenosing type was relatively localized; and the narrowing type may be early carcinoma. The lack of opacification of side branches appears to be one of the most important findings in the detection of early stages of carcinoma of the pancreas. Since there is considerable discrepancy between morphological and functional tests, both endoscopic pancreatography and a series of pancreatic function tests are necessary in the diagnosis of pancreatic disease.

6256 OBSERVATIONS DURING TREATMENT OF ACUTE PANCREATITIS WITH INSULIN AND GLUCOSE INFUSION. *(E.)* Hallberg, D.; Theve, N. O. (Karolinska Inst., Stockholm, Sweden). *Acta Chir. Scand.* 140(2):138-142, 1974.

Twenty patients with acute pancreatitis were treated only with i.v. drop infusion of 5.5% glucose solution with 20 IU/1000 ml of insulin. All patients had blood glucose levels above 100 mg/100 ml, elevated amylase values in blood and/or urine, and elevated free fatty acids in plasma. Of the 20 patients, 10 had a proven history of alcohol abuse and 12 had a positive x-ray examination for gallstones. The infusion rate was fast during the 1st hr (300-400 ml) and was then reduced according to the disappearance of abdominal pain. Fifteen patients became free from pain within 4 hr, 9 of these within 1 hr. In 3 patients the abdominal pain lasted 72 hr or longer, and in 2 patients with long-lasting elevation of amylase in urine, pain returned as soon as treatment was discontinued. These 2 patients later developed pancreatic cysts and underwent surgery. All patients were completely recovered at time of discharge. The beneficial effects of insulin and glucose are ascribed to the inactivation of the hormone-sensitive lipase present in adipose tissue where fat necrosis develops.

6257 MASSIVE HEMORRHAGE FROM THE CELIAC AXIS IN PANCREATITIS. *(E.)* Schecter, L. M.; Gordon, H. E.; Passaro, Jr., E. (VA Wadsworth Hosp. Ctr., Los Angeles, Calif.). *Am. J. Surg.* 128(2): 301-305, 1974.

Case reports are presented for 4 men, aged 30-73 yr, with chronic pancreatitis and massive hemorrhage from the celiac axis. Concomitant intra-abdominal hemorrhage was noted in 2 patients. One case marks the first reported incidence of a documented pseudoaneurysm of the left gastric artery secondary to chronic pancreatitis. Celiac axis arteriography was helpful in establishing the diagnosis and determining proper surgical management. Total gastrectomy with esophagojejunostomy had to be performed because of marked erosion, inflammation, and scarring of the fundus. Two other patients had pseudoaneurysms of the splenic artery; only 1 of these 2 patients had a pancreatic pseudocyst. Three patients survived. Extensive gastric resection was required in 3 patients. An early and continued aggressive diagnostic approach is needed in patients with chronic pancreatitis and/or pseudocyst and significant upper gastrointestinal bleeding.

6258 OBSERVATIONS ON GLUCAGON TREATMENT IN PANCREATITIS. *(E.)* Fleischer, K.; Kasper, H.; (Med. Clin., Univ. Wurzburg, Germany). *Scand. J. Gastroenterol.* 9(4):371-376, 1974.

Of 25 patients treated with glucagon (19 with 6-12 mg/day i.v. and 6 with the same dose of a sustained-action preparation i.m., for 3-12 days), 9 (5 males and 4 females, mean age 45 yr) had acute pancreatitis and 16 (14 males and 2 females, mean age 39 yr) had chronic relapsing pancreatitis. Abdominal pain was alleviated or disappeared in 12 of the 15 patients who suffered from it, and a persistent decrease in serum lipase activity occurred in 15 of 22 patients with abnormally high values. In 8 patients serum lipase activities increased again after glucagon had been discontinued, and in 1 patient lipase activity remained normal after the end of treatment. Serum lipase activities remained elevated for a longer period in a control group of 33 patients who did not receive glucagon therapy. Glucagon therapy had to be discontinued in 2 patients because of the development of nausea, crampy epigastric pain, and headaches. Since these symptoms disappeared after withdrawal of glucagon and recurred after renewed administration, it is concluded that they are side effects of glucagon. Blood sugar values increased only moderately during glucagon therapy except in 3 patients who had increases of between 200 and 300 mg/100 ml. Severe hemorrhagic necrotizing pancreatitis was discovered at autopsy in the 2 glucagon-treated patients who died. Although these findings demonstrate that glucagon has a beneficial effect on the intensity of abdominal pain and serum lipase activities in acute and chronic relapsing pancreatitis, there is no proof that it shortens the duration of the disease or improves the prognosis. It has been suggested that glucagon acts by inhibiting pancreatic secretion, restricting enzyme synthesis in the acinar cells, reducing intestinal motility, and decreases gastric acid secretion.

6259 PANCREATIC PSEUDOCYSTS IN CHILDREN. *(E.)* Moossa, A. R. (Univ. Chicago Hosp. Clin., Ill.). *J. Roy. Coll. Surg. Edinb.* 19(3):149-158, 1974.

In 10 children (4 boys and 6 girls, aged 3 to 16 yr), pancreatic pseudocysts developed as a result of trauma in 6 and papillary stenosis in 1; their etiology was unknown in 3 cases. All had some degree of epigastric pain and tenderness; 4 presented as acute abdominal emergencies needing urgent laparotomy after resuscitation; 1 had progressive abdominal distension and malaise of a few weeks duration; and others experienced repeated vomiting. A plain radiograph of the abdomen was helpful in only 1 case. Treatment consisted of conservative management in 2 cases, external drainage in 1, cystogastrostomy in 4, cystogastrostomy + partial cyst excision in 1, cystoduodenostomy + later cystogastrostomy in 1, and cystojejunostomy with a Roux-en-Y loop + later sphincterotomy in 1. The best results were obtained with transgastric posterior cystogastrostomy, which appears the safest operation. It is concluded that acute pancreatitis with or without pseudocyst formation must be considered in the differential diagnosis of acute abdominal emergencies in childhood. A raised serum amylase activity makes careful examination and palpation of the pancreas mandatory. Two noninvasive methods of diagnosing pancreatic pseudocysts without special preparation of the patient, scintiscanning with ^{75}Se-selenomethionine and echography, are of great help.

LIVER AND BILIARY TRACT

6273 LIVER ULTRASTRUCTURE IN ABETALIPOPROTEINEMIA: EVOLUTION OF MICRONODULAR CIRRHOSIS. *(E.)* Partin, J. S.; Partin, J. C.; Schubert, W. K.; McAdams, A. J. (Child. Hosp. Res. Fdn., Cincinnati, Ohio). *Gastroenterology* 67(1):107-118, 1974.

A 10-month-old boy was found to have abetalipoproteinemia, substantial hepatomegaly, and persistent elevation of SGOT and SGPT. Liver biopsies were obtained prior to and at 2, 14, and 20 months after initiation of treatment with a medium-chain triglyceride-substituted low fat diet. The initial liver biopsy contained 38% lipid, 91% of which was triglyceride. Hepatocytes contained large fat droplets which ruptured to form centrilobular fatty lakes. Ultrastructurally, the Golgi was nearly completely deficient in trans-Golgi vacuole formation. Endogenous triglyceride particles could not be found and the circum-Golgi smooth endoplasmic reticulum was absent. When the infant was fed a medium-chain triglyceride diet, steatorrhea improved and the liver cell cytoplasmic fat droplets became smaller and less numerous. During the 14 months of medium-chain triglyceride feedings, however, there was progression of the initially mild hepatic fibrosis to an advanced micronodular cirrhosis, and alcoholic hyalin appeared in the hepatocytes. It is suggested that the development of alcoholic hyalin may be related to the accumulation of 2-carbon fragments derived from medium-chain triglycerides as a result of defective hepatic triglyceride secretion. Because of the destructive but asymptomatic lesion seen in this infant's liver, liver function should be carefully investigated in all children with abetalipoproteinemia. Diagnostic liver biopsy is indicated if hepatomegaly or chemical signs of liver dysfunction persist, particularly if diet manipulation is contemplated.

6274 BENIGN CHOLESTATIC JAUNDICE OF PREGNANCY AND BENIGN CHOLESTATIC JAUNDICE FROM ORAL CONTRACEPTIVES. *(E.)* Drill, V. A. (G. D. Searle & Co., Skokie, Ill.). *Amer. J. Obstet. Gyn.* 119(2): 165-174, 1974.

In women with benign cholestatic jaundice of pregnancy, there appears to be a metabolic defect such that the increased secretion of estrogen and progesterone during pregnancy results in jaundice. Following delivery, the jaundice disappears, and there is no residual effect on liver function or liver histology. Cholestatic jaundice of pregnancy is not due to destruction of liver cells, but to interference with the secretory process, so that conjugated bilirubin accumulates in the blood stream and produces the jaundice. The administration of oral contraceptives to women with a history of cholestatic jaundice of pregnancy may result in a generalized pruritis or a cholestatic jaundice similar in nature to that which occurs during pregnancy. This jaundice, like that of a pregnancy, is benign, and liver function returns to normal when treatment is discontinued. Pruritis may be a prodromal sign for the development of cholestatic jaundice. In the nulliparous woman, the development of generalized pruritis during the use of oral contraceptives indicates that the patient may develop benign cholestatic jaundice if treatment is continued or if pregnancy occurs.

6275 GAMMA-GLUTAMYL-TRANSPEPTIDASE IN HEPATOBILIARY DISEASE — VALUE AS AN ENZYMATIC LIVER FUNCTION TEST. *(E.)* Cuschieri, A.; Baker, P. R. (Dept. Surg., Univ. Liverpool, England). *Br. J. Exp. Pathol.* 55(2):110-115, 1974.

The diagnostic and prognostic value of serum gamma-glutamyl-transpeptidase activity in hepatobiliary disease was investigated in 52 patients (19-68 yr) and 33 controls (24-56 yr) whose serum bilirubin, alanine-aminotransferase, albumin, and globulin values were normal. Gamma-glutamyl-transpeptidase activity in the controls averaged 14.8 mU/ml, whereas it was elevated in cryptogenic and alcoholic cirrhosis (53.8 mU/ml), chronic active hepatitis (240.6 mU/ml), extrahepatic biliary tract obstruction (156.0 mU/ml), primary biliary cirrhosis (greater than 200 mU/ml), and hepatic neoplasms (greater than 200 mU/ml). In cirrhosis, there was a significant decline in activity as the condition progressed, and very low values were found in terminal hepatic coma. In chronic active hepatitis, there was no significant difference between values observed during relapse and remission. After surgical correction of biliary tract obstruction, the enzyme activity remained elevated for 4-6 weeks, indicating limited use of the test in the early follow-up of patients so treated. Although a high serum level of gamma-glutamyl-transpeptidase activity was thus found to be associated with cholestatic disorders, determination of the level does not appear to contribute materially toward differentiation between biliary and parenchymatous disease.

6276 LONG-TERM INTRAARTERIAL INFUSION IN CHEMOTHERAPY OF LIVER CANCER: PRELIMINARY REPORT.

(Rus.) Klimenko, G. A. (Khar'kov Sci. Res. Inst. Gen. Emergency Surg., USSR). *Klin. Khir.* (7):20-25, 1973.

By means of retrograde percutaneous transfemoral catheterization of the celiac trunk and common hepatic artery, continuous intra-arterial infusions of 5-fluoro-uracil (FU) were administered to 6 patients with primary or secondary liver tumors for periods of 1-3 weeks. The daily dose of FU (10 mg/kg/day) was dissolved in 2000-2500 ml of 5% glucose solution containing insulin (1 U/5 g dry glucose), heparin (5000 U/liter), and other drugs (epinephrine, diphenhydramine hydrochloride, vitamins and, in some cases, procaine). Of these 6 patients, 3 showed subjective and objective responses to FU. These included one patient with a large hepatocellular carcinoma who developed hypoglycemic crises; glucose infusions were no longer required after administration of FU. In another patient with an inoperable adenocarcinoma of the hepatic portal and hepatic metastases, symptoms of obstructive jaundice disappeared after infusion of 10 g FU over a 2-week period. Therapy also reduced serum bilirubin levels and normalized serum transaminase levels, but the patient developed ascites, hypoalbuminemia, and bone marrow depression, possibly because FU leaked into the systemic circulation due to difficulty in positioning the catheter. Pain was alleviated in a 3rd patient with cancer of the papilla of Vater and hepatic metastases. The unsatisfactory effect of therapy in the other 3 patients may have been due to progressive disturbances in liver function, growth of the primary tumor, and administration of inadequate doses of FU, but these patients were poor candidates for chemotherapy in the first place. They consisted of a patient with a pancreatic carcinoma which had invaded the liver, a patient with a primary liver tumor involving both lobes, and one with a tumor of the head of the pancreas and multiple hepatic metastases.

6277 KINETICS OF RADIOACTIVE COPPER IN WILSON'S DISEASE.

(Ger.) Willvonseder, R.; Goldstein, N. P.; Tauxe, W. N. (Mayo Clin., Rochester, Minn.). *Wien. Z. Inn. Med.* 54(5/6):226-233, 1973.

Plasma incorporation, hepatic uptake, urinary and fecal excretion, and whole-body retention of ^{64}Cu or ^{67}Cu were investigated in 36 homozygous carriers of the gene for Wilson's disease, 24 of their heterozygous parents, and 28 normal controls. The diagnosis of Wilson's disease was confirmed either by the finding of Kayser-Fleischer rings or a pathological decrease in serum ceruloplasmin associated with typical neurological symptoms and liver disease. Plasma radioactivity decreased during the first hr after i.v. injection of ^{64}Cu or ^{67}Cu in normal controls and heterozygotes, after which the radioactivity increased. Although heterozygotes incorporated less Cu in their plasma than controls, the shape of incorporation curves for both of these groups was similar. In contrast, practically no plasma incorporation of Cu occurred in untreated homozygotes with manifest Wilson's disease, and plasma radioactivity progressively decreased. Liver scans revealed that 50% of the injected Cu was present in the liver of controls 55 min after injection. Within 3 days both controls and heterozygotes had catabolized some of this copper. Hepatic uptake of Cu progressively increased in homozygotes and reached extremely high values in patients with presymptomatic Wilson's disease. Although little or no Cu was excreted in the urine of most of the subjects studied, fecal excretion increased progressively in normal subjects and was lower in heterozygotes than in controls. The lowest values for fecal excretion were obtained in patients with presymptomatic Wilson's disease. Untreated homozygotes with manifest Wilson's disease excreted more Cu in the urine than any of the other groups, but little or no Cu was found in their stools. Whole-body retention differed significantly between homozygotes, heterozygotes, and controls. With ^{64}Cu the mean biological half-lives were 97.0 ± 29.6 days for untreated homozygotes, 29.4 ± 17.0 days for heterozygotes, and 17.0 ± 3.2 days for controls. These findings indicate that Cu is normally bound to ceruloplasmin in the liver. The liver of patients with Wilson's disease is unable to incorporate Cu into ceruloplasmin so that unbound Cu accumulates in the liver. The Cu-uptake mechanism, which is present in the normal liver, becomes decompensated in manifest Wilson's disease, and Cu overflows into the urine and the tissues.

6278 FANCONI'S DISEASE AND LIVER CANCER.

(Fr.) Cattan, D.; Kalifat, R.; Wautier, J. L.; Meignan, S.; Vesin, P.; Piet, R. (Nouvel Hosp., Villeneuve-Saint Georges, France). *Arch. Fr. Mal. App. Dig.* 63(1):41-48, 1974.

Fanconi's disease was diagnosed in an 8-yr-old girl who had pancytopenia associated with congenital anomalies (growth retardation, microcephalia, skin pigmentation, bilateral syndactylia of the lower extremities, and left renal atrophy). The patient was splenectomized when she was 9 yr old and was treated by transfusions; no androgens were ever administered. At the age of 23 yr the patient was hospitalized with hepatomegaly and a positive α-fetoprotein test. Laparoscopy revealed cirrhosis with polychromatic masses and multiple whitish nodules over the entire surface of the liver and signs of portal hypertension. Many cold spots were detected in the liver by Tc scanning. These spots filled up during scanning with selenomethionine. Hemorrhagic ascites and a hemorrhagic pleural effusion developed on the 15th day of hospitalization and rapidly reappeared after paracentesis. The patient died 2 months after admission. Autopsy showed a hepatoma with some areas of cholangiomatous differentiation which developed in association with micro- and macronodular cirrhosis and hemochromatosis, intrahepatic cholestasis, and bile production by the tumor. Multiple metastases were detected in the lungs, pleura, lymphatics, and mediastinal lymph nodes. These metastases also produced bile. The kidneys also contained many bile deposits in the epithelium of the excretory tubules. A duodenal ulcer had perforated and penetrated the head of the pancreas. This is the 5th reported case of Fanconi's disease associated with liver cancer in the literature. This case casts doubt on the hypothesis that the liver cancer is caused by androgen therapy. It is suggested that a genetically transmitted susceptibility to cancer might be present in patients with Fanconi's disease and their families.

6279 PRIMARY CARCINOMA OF THE LIVER. *(E.)* Honjo, I.; Mizumoto, R. (Kyoto Univ. Med. Sch., Japan). *Am. J. Surg.* 128(1):31-36, 1974.

Hepatic resection for carcinoma of the liver has only rather recently been established as a standardized surgical procedure, and this report analyzes the overall handling (including resection) of 76 patients with histologically proven primary cancer of the liver over a 22-yr period. Seventy-one of the patients were adults (27-75 yr old) and 5 were infants and children (5.5 months to 13 yr); the ratio of males to females was 3.4:1. Of the 76 patients, 57 had hepatocellular carcinoma, 15 cholangiocellular carcinoma, and 4 showed a mixed type. Surgical exploration on 71 patients included hepatic resection in 23 (32%), ligation of the portal branch in 8, ligation of the hepatic artery in 7, and exploratory laparotomy alone in 33 cases. Diagnosis in the remaining 5 of the 76 patients was established by autopsy or percutaneous needle biopsy. Cirrhosis of the liver was clearly evident in 28 of the 57 patients with hepatocellular carcinoma. Of 10 cirrhosis patients who underwent hepatic resection, 2 died from hepatic coma within 2 months; 2 showed a delayed recovery of liver function after hepatic lobectomy; and the remaining 6 patients survived with no remarkable changes after segmental resection of procedures of lesser magnitude. One of them was well for 17 yr and 5 months after lateral segmentectomy until he was killed in a traffic accident. Operative mortality in all patients who underwent hepatic resection was 9%, and the survival rates were 43% for 1 yr, 22% for 3 yr, and 13% for 5 yr. For patients with nonresectable cancer, ligation of one of the main portal branches supplying the main tumor resulted in some improvement of their prognosis. Thus, this more aggressive approach to surgical treatment of liver tumors, hepatic resection, promises a greater chance for success.

6280 LIVER FUNCTION AND HISTOLOGY IN ASYMPTOMATIC CHINESE MILITARY PERSONNEL WITH HEPATITIS B ANTIGENEMIA. *(E.)* Anderson, K. E.; Sun, S. C.; Berg, H. S.; Chang, N. K. (U.S. Navel Med. Res. Unit No. 2, Taipei, Taiwan). *Am. J. Dig. Dis.* 19(8):693-703, 1974.

A 1-year survey of 1433 apparently healthy Chinese military personnel (91% aged 15-25 yr) showed a high prevalence (12.7%) of hepatitis B antigen similar to other Taiwan studies. The reasons for this widespread prevalence are unknown, but maternal-fetal transmission, frequent injections, and poor sanitation may be partly responsible. There was a statistically significant association between antigen presence and SGOT elevation. Of 44 men (aged 20-21 yr) selected for detailed study of the liver function and histology, 5 had symptoms suggestive of viral hepatitis; in 4, these had occurred 1-5 yr previously but the 5th subject still had acute as well as chronic symptoms. Mild SGOT elevation was present in 13 cases and in 17 BSP retention exceeded 5% at 45 min; a significant relation between SGOT increase and abnormal BSP retention was observed. Liver biopsies demonstrated portal tract inflammation and expansion; lobular histopathology (including cell swelling, focal inflammation, and necrosis); and eosinophilic bodies, although these changes were often mild and nonspecific. Cirrhosis was not found in any case. Histologically the 44 cases were classified as chronic aggressive hepatitis (1), chronic persistent hepatitis (9), lobular hepatitis (9), nonspecific changes (22), and normal (3). These results indicate that the majority of young Chinese men with asymptomatic hepatitis B antigenemia do not have severe chronic liver disease; however, follow-up studies over several years will be required to determine accurate long-term prognoses in these carriers.

6281 HEPATIC CHANGES AFTER SMALL-INTESTINAL BYPASS FOR MORBID OBESITY. *(E.)* Kern, W. H.; Payne, J. H.; Dewind, L. T. (Hosp. Good Samaritan, Los Angeles, Calif.). *Am. J. Clin. Pathol.* 61(6):763-768, 1974.

Liver biopsies obtained from 30 patients during intestinal bypass procedures for morbid obesity were compared with biopsies taken up to 133 months after the shunt. Fatty change, expressed as the percentage of cells containing fatty cytoplasmic vacuoles, and the presence of inflammation and fibrosis were noted. All but 2 of the 30 patients had some evidence of fatty metamorphosis in the 1st biopsy specimen. In the 8 patients (women, aged 20-43 yr) who underwent jejunocolic shunts and in 10 of the 22 (4 men and 18 women, aged 23-48 yr) with jejunoileal shunts, fatty changes were more severe in the 2nd biopsy specimen. Of the 10 jejunoileal shunt patients with more severe changes, 5 were biopsied 18 months or sooner after surgery and 5 following weight stabilization (2 yr or later). In 8 other patients rebiopsied after weight stabilization, hepatic parenchymal changes remained the same in 2 and improved in 6. A significant decrease in fatty change was observed in the 3 patients who had 3rd biopsies 12-15 months later. The extent of inflammatory change did not differ significantly between groups, but 13 patients (11 with jejunoileal shunts and 2 with jejunocolic shunts) had a slightly greater periportal fibrosis at time of the 2nd biopsy. None of these patients developed cirrhosis.

6282 LIVER STUDIES IN THE THOROTRAST PATIENTS—LABORATORY AND CLINICAL FINDINGS (STUDY OF 175 CASES). *(E.)* Tavares, M. H.; Saragoca, A.; da Silva Horta, J. (Univ. Lisbon, Fac. Med., Portugal). *Proc. 3rd Int. Meeting Toxicity Thorotrast* 294:212-218, 1973.

This study on effects of Thorotrast utilized records of laboratory tests and clinical studies on the liver since systemic injection of this drug results in deposits in the reticuloendothelium system. Data from 175 unselected patients (86 men and 89 women, aged 22-87 yr) injected with thorium dioxide 10-41 yr earlier were analyzed. Doses of Thorotrast ranged from 4-70 ml, but were unknown in 19 cases. Clinical complaints were most often related to gastrointestinal pathology, mainly the liver. Laboratory tests disclosed serum dysproteinemias: low albumin (70.9% incidence); increased α-2-globulin (69.3%); and increased γ-globulin (71.1%); as well as increased levels of blood alkaline phosphatase (70.1%). The α-fetoprotein levels were negative in all 10 cases in which it was possible to perform this test. Among the 25 cases with histological liver examination, 11 liver tumors were found: 4 hemangioendotheliomas, 5 cholangiocarcinomas, and 2 adenocarcinomas. The remaining 14 cases disclosed hepatic fibrosis. The liver tumors appeared only in patients with 25 or more yr since injection.

6283 INTRAHEPATIC HEMATOMA: A COMPLICATION OF PERCUTANEOUS LIVER BIOPSY. A REPORT ON THE INCIDENCE OF POSTBIOPSY SCAN DEFECTS. *(E.)*

Raines, D. R.; Van Heertum, R. L.; Johnson, L. F. (Tripler Army Med. Ctr., San Francisco, Calif.). *Gastroenterology* 67(2):284-289, 1974.

An intrahepatic hematoma occurred after percutaneous liver biopsy in a 62-yr-old woman who had possible liver involvement due to chronic alcoholism. A complete blood count and coagulation studies (prothrombin time and partial thromboplastin time) were normal, but liver function tests were abnormal. Ten days after the biopsy, a liver scan showed a large defect laterally on the lobe. Hepatic angiography confirmed the scan lesion and also demonstrated an intrahepatic hemangioma. Peritoneoscopy revealed fresh, dense hemorrhagic adhesions involving the right liver lobe at the site of the previous percutaneous liver biopsy. Serial hepatic scanning and an arteriogram demonstrated complete resolution of the hematoma over a 3-month period. The hemangioma remained unchanged. In a subsequent 7-month prospective study of 40 patients, 3 (7%) had postbiopsy scan defects not present on the prebiopsy scan. To avoid diagnostic confusion and unnecessary diagnostic procedures, liver scans should be obtained prior to percutaneous liver biopsy.

6284 AN ALGORITHM FOR MONITORING AND MANAGING DRUG HEPATOTOXICITY. *(E.)*

Hofmann, A. F.; Thistle, J. L. (Mayo Clin., Rochester, Minn.). *Gastroenterology* 67(2):309-313, 1974.

A systemic schedule for monitoring and managing drug hepatotoxicity is based on SGOT analyses at 2 and 4 weeks. If the SGOT value is increased on 2 occasions a liver biopsy is done and the drug (e.g., chenodexoycholic acid) discontinued if liver damage is confirmed. If there is no damage, the patient will be managed according to monthly SGOT values. If 2 consecutive SGOT values are normal, the drug will be continued and the patient's condition reevaluated at 6-month intervals. Failure of SGOT to return to normal will be an indication for decreasing the drug dose by ½ on 2 occasions. SGOT and alkaline phosphatase are monitored during and after cessation of drug administration, until SGOT values return to normal. The schedule detects both unpredictable hepatotoxic reactions and predictable or more chronic reactions.

6285 HEPATIC LIPID IN REYE'S SYNDROME: HISTOCHEMICAL AND ULTRASTRUCTURAL CHARACTERISTICS. *(E.)*

Brown, R. E.; Johnson, F. B.; Mullick, F. G. (J. C. Blair Mem. Hosp., Huntingdon, England). *Pa. Med.* 77(6):39-41, 1974.

Histochemical and ultrastructural studies were carried out on liver sections from 4 patients with Reye's syndrome in an attempt to characterize the lipid within the parenchymal cells. This lipid was generally distributed throughout the lobule, but occasionally there was noticeably less lipid in periportal hepatocytes. Within cells, lipid droplets were usually small and uniform in appearance, did not displace the hepatocyte nucleus, and did not generally fill the cytoplasm. Their numbers varied from cell to cell within each case. The absence of histochemically demonstrable amounts of glycolipids, phospholipids, free fatty acids, and cholesterol and the absence of cholesterol esters suggested that the accumulated lipid was predominately neutral lipid, probably triglyceride. This is consistent with the results of chromatographic and chemical analyses of hepatic lipids, with studies of blood lipids in Reye's syndrome, which indicated no hyperlipoproteinemia, hypercholesterolemia, or hyperphospholipidemia, and with known physiopathic aspects of the disease. Ultrastructurally, a characteristic of the accumulated lipid droplets was the occasional presence of osmiophilic dense material, possibly lipomicrons, at the interface between droplets and hepatocyte cytoplasm. The results are further evidence for excessive lipolysis with mobilization of fatty acids in Reye's syndrome and thus support the argument for antilipolytic therapy.

6286 BIREFRINGENCE OF HEPATIC PIGMENT DEPOSITS IN ERYTHROPOIETIC PROTOPORPHYRIA. *(E.)*

Klatskin, G.; Bloomer, J. R. (Yale Univ. Sch. Med., New Haven, Conn.). *Gastroenterology* 67(2):294-302, 1974.

Liver specimens from 7 patients with erythropoietic protoporphyria showed that deposits of protoporphyrin characteristic of this condition were crystalline under the electron microscope and exhibited a distinctive type of birefringence not shared by any other hepatic pigments when viewed by the polarization microscope. This birefrigence was readily visible in routine fixed and stained paraffin-embedded sections, and was as sensitive an indicator as red fluorescence. No such protoporphyrin birefringence was seen in 45 control patients whose liver contained bile, hemosiderin, lipofucsin, Dubin-Johnson pigment, melanin, anthrocotic pigment, schistosomal pigment, and Thorotrast. Liver samples from 4 patients with other forms of porphyria which were unaccompanied by hepatic pigment deposits were also studied because 3 of the specimens demonstrated red fluorescence. All 4 were negative for birefrigence. This technique is rapid, highly sensitive, and specific for the identification of hepatic protoporphyrin. In contrast to fluorescence microscopy polarization examination does not require frozen sections or a fluorescence microscope and can be carried out with any standard light microscope fitted with a pair of polarizing filters. When used with routinely fixed and stained paraffin-embedded sections, polarization microscopy permits more precise localization of the protoporphyrin deposits, however minute.

6287 LIVER IRON CONCENTRATION, STAINABLE IRON, AND TOTAL BODY STORAGE IRON. *(E.)* Barry, M. (Roy. Free Hosp., London, England). *Gut* 15(5): 411-415, 1974.

Over a 5 yr period, liver iron concentration was determined chemically in 154 liver biopsies and the findings compared with the routine histological assessment of stainable parenchymal iron, performed by a independent observer. There was a significant correlation between liver iron concentration and histochemical grading but the relationship did not have a normal linear form. Absence of stainable iron corresponded to liver iron concentrations below the mean value for control male subjects (77 μg/100 mg dry liver). In general, grade 1 siderosis corresponded to liver iron concentrations in the upper part of the control range and grade 2 siderosis to marginally elevated values. The transition from grade 2 to grade 3 (submaximal) siderosis represented a sharp increase in liver iron concentration; and as grade 3 siderosis corresponded to a wide range of chemical values, it is also the most difficult histochemical grade to interpret in quantitative terms. Grade 4 siderosis invariably indicated heavy iron excess. There was a close correlation between liver iron concentration and measurements of total body storage iron obtained by quantitative phlebotomy in patients with idiopathic hemochromatosis and by determination of diethylenetriamine pentaacetic acid chelatable body iron in a variety of iron-loading disorders.

288 HEMOLYTIC ANEMIA OF WILSON'S DISEASE. *(E.)* Iser, J. H.; Stevens, B. J.; Stening, G. .; Hurley, T. H.; Smallwood, R. A. (Austin Hosp., ictoria, Australia). *Gastroenterology* 67(2):290-93, 1974.

Case reports are presented of a 27-yr-old woman and a 28-yr-old man with Wilson's disease who were admitted with severe hemolytic anemia and evidence of Liver decompensation. In the 2nd patient, copper studies and severe coagulation abnormalities were consistent with Wilson's disease and prompt slit-amp examination confirmed the presence of Kayser-'leischer rings. Because of the certainty of diagosis and the grossly abnormal coagulation profile, iver biopsy was not performed. The patient was uccessfully treated with penicillamine (1 g/day intially, increased to 2 g/day) and is now symptom ree. The 1st patient, in whom the diagnosis was elayed 2 months, succumbed following a 2nd hemolyic episode during which hemoglobin fell to 6.9 g/100 l and bilirubin rose to 42 mg/100 ml. Subsequent nvestigations showed that each patient had a sibling ith Wilson's disease. In both patients, release f copper into plasma and urine coincided with epiodes of hemolysis. Serum "free" copper in the man as approximately 120 μg/100 ml, several times the evel normally found in Wilson's disease. This increased filterable fraction may have accounted for the high 24-hr urinary excretion (5676 μg). In the woman, a urinary copper level of over 10,000 μg/24 hr during the 2nd hemolytic episode suggested that a large copper flux occurred. In case 2, calculations assuming rapid red cell destruction indicated that copper was probably released from red cells during intravascular hemolysis. This study indicates the importance of early diagnosis of Wilson's disease when severe hemolysis and hepatic decompensation occur together.

6289 CLEARANCE OF ANTIPYRINE-DEPENDENCE OF QUANTITATIVE LIVER FUNCTION. *(E.)* Andreasen, P. B.; Ranek, L.; Statland, B. E.; Tgystrup, N. (Univ. Hosp., Copenhagen, Denmark). *Eur. J. Clin. Invest.* 4(2):129-134, 1974.

Plasma clearance of antipyrine (100 mg/ml i.v. for 5 min) was determined in 13 patients (aged 22-75 yr) with liver disease, and compared with the results of other quantitative liver function tests. Nine patients (aged 26-59) without liver disease served as controls. Diagnosis in the 13 patients was alcoholic cirrhosis (5), idiopathic cirrhosis (5), primary biliary cirrhosis (2), halothane hepatitis (1), and extrahepatic biliary obstruction (1). Clearance of antipyrine was significantly lower in patients with liver disease than in controls (18.5 and 58.6 ml/min, resp.). Among patients with liver disease, 7 with severely reduced capacity for work had significantly lower clearance of antipyrine than nonincapacitated patients (12.5 and 25.4 ml/min, resp.). Antipyrine clearance was significantly correlated with galactose elimination capacity, serum albumin values, and prothrombin values. The results indicate that the drug-metabolizing capacity of the liver changes in parallel with other metabolic functions. Therefore, the clearance of antipyrine may be a useful quantitative test of liver function.

Nonviral Hepatitis and Hepatic Injury

6353 LIVER FUNCTION IN WORKERS HAVING HIGH TISSUE STORES OF CHLORINATED HYDROCARBON PESTICIDES. *(E.)* Morgan, D. P.; Roan, C. C. (Inst. Agr. Med., Univ. Iowa, Oakdale). *Arch. Environ. Health* 29(1):14-17, 1974.

Liver cell injury and induction of drug-metabolizing enzymes due to exposure to chlorinated hydrocarbon pesticides were checked in 28 men working from 5 to 22 yr in the formulation or application of agricultural chemicals and showing high tissue stores of DDT and its metabolites (up to 660 ppb DDT + DDE serum concentration), and in 43 workers engaged principally in termite control and showing exceptional blood levels of dieldrin (up to 313 ppb) due to cumulative absorption over several years. Controls were 56 male subjects with no more than ordinary household exposure to pesticides (DDT 4, DDE 52, and dieldrin 0.3 ppb in serum). The use of serum concentrations of DDT and dieldrin to reflect tissue storage has empirical support. Five serum enzyme activities (SGOT, SGPT, LDH, alkaline phosphatase, and creatine phosphokinase) were measured to gauge liver cell damage; urinary excretion of D-glucaric acid was observed to determine possible induction effects. Statistical comparisons of means for pesticide-exposed subjects with control means revealed substantial and significant differences in all three serum pesticide concentrations, but no significant differences in serum enzyme activity tests or D-glucaric acid excretion between exposed and nonexposed groups. Neither the serum enzymes nor the D-glucaric acid excretion were significantly correlated with the concentrations of pesticides in the serum. The results obtained here show no evidence that high tissue stores of DDT, DDE, or dieldrin damage liver cells, or stimulate the hepatic synthesis of D-glucaric acid.

6354 HEPATIC INJURY ASSOCIATED WITH PENICILLIN THERAPY. *(E.)* Goldstein, L. I.; Ishak, K. G. (Armed Forces Inst. Pathol., Washington, D.C.). *Arch. Pathol.* 98(2):114-117, 1974.

A 42-yr-old man was given phenoxymethyl penicillin (250 mg 4 times/day) after presenting with joint pains of 3 days' duration. After 8 days of treatment, the patient developed a syndrome resembling serum sickness, with fever, leukocytosis, and arthralgias of the knees, ankles, and small joints of the hand. The only biochemical abnormality reflecting hepatic injury was increased serum alkaline phosphatase activity (80-96 U). The hepatic origin of the rise in serum alkaline phosphatase was established by starch gel electrophoresis and determinations of leucine aminopeptidase (70 mμ/ml) and 5'-nucleotidase (10.5 U). Light microscopy of sections from the percutaneous hepatic biopsy specimen showed minimal accumulation of bile pigment in ventrilobular hepatocytes together with slight parenchymal injury. Electron microscopy delineated the site of injury as mainly canalicular and pericanalicular. The injury was predominantly that of intrahepatic cholestasis, but was not reflected by jaundice or hyperbilirubinemia.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

6364 ACTIVITY OF COBALT-ACTIVATED SERUM ACYLASE IN VIRAL HEPATITIS. *(Pol.)* Fojt, E.; Gabrys, A.; Fojt, E. (Silesian Acad. Med., Katowice, Poland). *Pol. Tyg. Lek.* 28(52):2043-2045, 1973.

Cobalt-activated acylase activity was determined in sera of 47 patients with viral hepatitis (group I), 12 with other hepatobiliary diseases (group II), and 4 with other diseases (neoplasms of the colon and pancreas, mumps, and pancreatitis) (group III). A significant rise in activity was noted in group I, especially during the first stages of the disease. In 83% of patients of this group, enzyme activity exceeded 0.7 U; values varied between 0-12.8 U with an arithmetic mean of 3.3 ± 2.7 U. In group II activity exceeded 0.7 U in only 42% of patients, never exceeded 1.6 U, and the arithmetic mean was 0.75 ± 0.6 U. In group III values never exceeded 0.7 U with an arithmetic mean of 0.4 ± 0.3 U. These results suggest that values above 1.6 U are specific for viral hepatitis. A comparison with SGPT activity in these patients indicated that in the early stages of the disease cobalt-activated serum acylase is more specific for viral hepatitis than SGPT activity. It is suggested that determination of cobalt-activated acylase activity be included as a routine test for differential diagnosis of viral hepatitis.

6365 ON THE RARE ayr PHENOTYPE OF HEPATITIS B ANTIGEN. *(E.)* Le Bouvier, G. L.; Bancroft, W. H.; Holland, P. V. (Yale Univ. Sch. Med., New Haven, Conn.). *Intervirology* 1(5/6):405-408, 1973.

The rare, recently identified *ayr* phenotype of hepatitis β antigen was detected in the serum of a carrier in New Guinea. All 3 determinants were apparently present together on the same antigenic particle. The *a* and the *y* determinants reacted as expected, but the behavior of the *r* was unusual. Testing by immunodiffusion or counterelectrophoresis indicated that, in this particular serum, the antigenic particles have unusual *r*-reactive sites which take up certain classes of anti-*r* molecules in such a way as to prevent their interaction with *r* sites on adjacent particles. This is the 12th case of the *ayr* phenotype found in the Far East, the home of the *r* determinant in the *adr* form of the phenotype. Thus, preexistance of the postulated viral *r* gene may be a necessary conditon for appearance of the *ayr* phenotype. The conjunction of *y* and *r* determinants could occur in three principal ways: by *d*→*y* mutation in an hepatitis B virus stain of *adr* genotype; by phenotypic mixing of separate, but simultaneously infecting, *adr* and *ayw* viral genomes; and genetic reassortment, resulting in formation of a 'new' virus of genotype *ayr* in individuals infected, at some time, with both *adr* and *ayw* viruses.

6366 CHANGES IN SERUM FREE FATTY ACID LEVELS IN PATIENTS WITH VIRAL HEPATITIS. *(Pol.)* Tkaczewski, W.; Dworniak, D.; Karasek, E. (Warsaw Acad. Med., Poland). *Pol. Tyg. Lek.* 28(49):1928-1929, 1973.

Serum free fatty acid levels were determined at weekly intervals in 20 patients with viral hepatitis (13 women and 7 men, aged 20-50 yr), and the results were compared to values obtained from 20 healthy controls. During the first 2 weeks of illness, serum free fatty acid levels were increased to 912 ± 221.7 and 676 ± 255.4 μEq/liter resp. compared to control levels of 493 ± 137.8 μEq/liter. The extent of change in serum free fatty acid levels was independent of change in SGPT activity, bilirubin or β-lipoprotein levels, or the thymol turbidity test. Free fatty acid levels returned to normal sooner than the other biochemical parameters studied.

6367 HEPATITIS B-SPECIFIC DNA POLYMERASE ACTIVITY DURING POST-TRANSFUSION HEPATITIS. *(E.)* Kaplan, P. M.; Gerin, J. L.; Alter, H. J. (Rockville Lab. Mol. Anat. Program, Oak Ridge Natl. Lab., Rockville, Md.). *Nature (Lond.)* 249(5459):762-764, 1974.

Plasma samples from patients receiving multiple transfusions after surgery were analyzed for Australia antigen (HB Ag), anti-HB Ag, SGPT, and HB Ag-specific DNA polymerase activity. In a group of 3 patients tested, 1 patient developed posttransfusion type B hepatitis after receiving 19 units (500 ml each) of whole blood, 1 unit of which was positive for HB Ag by radioimmunoassay but negative by counterelectrophoresis. In this patient the first sign of infection was detected by a rise in HB Ag on day 25 after transfusion. On day 32, DNA polymerase activity was detected in serum which was concentrated 10-fold and in unconcentrated serum on day 39. SGPT elevation began on day 60. Peaks were reached on day 46 for polymerase, on day 58 for HB Ag, and on day 72 for SGPT. HB Ag and polymerase activity had normalized by day 185, while SGPT was still slightly elevated at this time. In another group of 11 patients, 7 of the 9 who developed posttransfusion hepatitis B (as indicated by the presence of HB Ag and elevated SGPT) had detectable plasma DNA polymerase activity during acute infection. In all cases, the elevated polymerase appeared slightly after the first detection of HB Ag, but preceded signs of liver damage as measured by raised SGPT levels. No polymerase activity was found in a patient with HB Ag-negative posttransfusion hepatitis or in 4 controls, and none of these 5 developed anti-HB Ag. However, nonspecific polymerase activity was exhibited by 1 of the controls as well as by 1 of 2 patients with HB Ag-positive posttransfusion hepatitis considered negative for DNA polymerase. These results show that in most cases HB Ag-specific DNA polymerase activity can be detected in plasma from acutely infected individuals. Peak levels of such activity were higher in acutely infected individuals than in most carriers. The transient nature of enzyme-containing Dane particles in blood and the time at which peak activity was found resembles viremias associated with other viral diseases. These data support the hypothesis that the Dane particle is the virus of hepatitis B. If this is true, then the actual titer of infectious virus in an HB Ag-positive serum may correlate better with the level of specific DNA polymerase than with the titer of HB Ag.

6368 α-FETOPROTEIN IN VIRAL HEPATITIS IN CHILDREN.

(Rus.) Silishcheva, N. N. (Astrakhan Med. Inst., USSR). *Pediatriia* (5):18-21, 1973.

By using a modification of Ochterlony's double diffusion technique, α-fetoprotein (AFP) was determined in serum for 598 children, aged 3 months to 15 yr, with viral hepatitis. Among the 562 children over 1 yr old, only an 8-yr-old boy with protracted hepatitis associated with hemorrhagic diathesis had a positive test for AFP. This test remained positive for 3 1/2 months. In contrast, AFP was detected in sera from 16 of the 36 infants 1 yr old or less. Of these 16 children, 10 had severe hepatitis with marked changes in liver function. Three infants became precomatose and 1 of the 3 fell into an hepatic coma and died. However, of the 5 infants who died, only 2 were able to produce AFP and 1 was found to have cirrhosis with marked regenerative changes at autopsy. In general, AFP appeared in the serum during the acute period when patients began to improve, i.e., at the onset of parenchymal regeneration. It is suggested that AFP determinations might have prognostic value in infants in this age group. In all but 3 patients AFP was still present in the serum after jaundice had disappeared and all clinical and biochemical parameters had normalized. In some patients AFP did not appear until 9-14 weeks after onset of symptoms; most of these patients were premature, had contracted hepatitis during the first 3 months of life, or had severe forms of the infection. No correlation was found between changes in AFP and the results of liver function tests. It is possible that with more sensitive techniques, such as immunoautoradiography, low titers of AFP might have been detected in serum from the remaining infants under 1 yr old.

6369 CHANGES IN SERUM LIPOPROTEINS AND LIPIDS IN HEPATITIS.

(Ger.) Schmitz, J.; Kahlke, W. (Med. Clin., Univ. Heidelberg, Germany). *Dtsch. Med. Wochenschr.* 98(51):2436-2439, 1973.

Serum triglyceride levels were abnormally elevated to values above 200 mg/100 ml 1-10 days after hospitalization of 45 patients with a confirmed diagnosis of acute viral hepatitis. These values had normalized before discharge (days 21-45) in 29 patients but remained elevated in 5. Serum cholesterol levels of less than 250 mg/100 ml were found in 37 patients at admission. At discharge 14 had elevated cholesterol values and 13 had values below 250 mg/100 ml. α-Lipoproteins were absent or present only in very low concentrations during the acute stage of hepatitis. No pre-β-lipoproteins were detected in most patients; 12 had reduced levels and 5, normal levels. Serum triglyceride values were elevated in 7 of the 12 patients with only low concentrations of pre-β-lipoproteins. In cases in which no pre-β-lipoprotein band was found on electrophoresis, a broader than normal β-lipoprotein band was present. Ultracentrifugation of this band showed that it consisted of 2 fractions: one with a very low density (< 1.006) and another with a low density (1.006-1.063). Thus, the pre-β-lipoprotein band did not disappear, but its electrophoretic mobility was reduced and it migrated in the β-lipoprotein region. The atypical lipoprotein pattern gradually normalized in all patients, including the 4 who had elevated serum triglyceride levels at both admission and discharge and who could have had IV hyperlipoproteinemia.

6370 HEPATITIS B ANTIGEN: NEW TECHNICS FOR THE REDUCTION OF POSTTRANSFUSION HEPATITIS.

(E.) Gitnick, G. L.; Koretz, R. L. (Univ. California., Los Angeles). *Am. J. Gastroenterol.* 61(5):366-370, 1974.

Two recently developed methods for detection of hepatitis B antigen (HB Ag), red cell agglutination and radioimmunoassay, were compared with counterelectrophoresis in an attempt to find a more sensitive technique for identification of HB Ag and thus, possibly prevent posttransfusion hepatitis. During a 7-month period, all units of blood used for transfusion were first tested for HB Ag by the counterelectrophoresis method, and only negative samples were transfused. Two weeks later, 6400 units of this stored negative blood were re-screened for HB Ag by red cell agglutination and by radioimmunoassay. A total of 138 units (2.2%) was found to be positive for HB Ag: 106 (1.1%) by the 1st method alone: 8 (0.1%) by the 2nd method alone; and 24 (0.4%) by both assays. Over a 9 month follow-up period, 70 patients (40 males and 30 females, aged 15-85 yr) who received HB Ag-positive blood were checked for levels of SGPT, bilirubin, HB Ag, and hepatitis B antibody (HB Ab) at 2 week intervals. Hepatitis developed in 27 of the 70 subjects (39%), and 6 others had positive tests for HB Ab. Of the 17 patients who received red cell agglutination-positive blood, 16 (94%) developed hepatitis, antibody conversion, or an HB Ag carier state, while only 20 of the 53 recipients (38%) of radioimmunoassay-positive blood showed evidence of exposure to hepatitis B. Of the 19 controls (matched for age, race, and sex) who received HB Ag-negative blood, as tested by red cell agglutination and radioimmunoassay, 9 developed hepatitis and 1 HB Ab. These results revealed that counterelectrophoresis gives a significant percentage of false-negative reactions for HB Ag-positive blood. Of the 2 newer methods, radioimmunoassay is more sensitive test than counterelectrophoresis for HB Ag, but the red cell agglutination technique correlates more closely with disease transmission.

Chronic Hepatitis

6387 IMMUNOTHERAPY WITH ANTIBODY, LYMPHOCYTES AND TRANSFER FACTOR IN CHRONIC HEPATITIS B.

(E.) Kohler, P. F.; Trembath, J.; Merrill, D. A.; Singleton, J. W.; Dubois, R. S. (Univ. Colorado Med. Ctr., Denver). *Clin. Immunol. Immunopathol.* 2(4): 465-471, 1974.

In an effort to modify chronic hepatitis B by immunological procedures, the efficacy of adoptively transferred humoral and cell-mediated immunity was studied in 3 patients. Over a 7-day period the first patient, a female with renal failure and chronic active hepatitis, received 10 units of human plasma which had a passive hemagglutination hepatitis B antibody (HB Ab) titer of 65,540. Before treatment of the patient, her serum HB Ab was undetectable and her serum hepatitis B antigen (HB Ag) titer was 128. The HB Ab titer increased to a plateau of about 1024 during most of the period of administration of the plasma, thereafter gradually decreasing. The HB Ag titer fluctuated during this period, later dropping along with the HB Ab titer. Coexistent antigen and antibody persisted for over 4 months. Clinically, there was no change in the patient's liver function. The second patient, a female asymptomatic chronic antigen carrier, received 8 x 10^9 lymphocytes from a donor who had recovered from hepatitis B 8 months previously. This patient showed signs of transient acute hepatitis as revealed by an increase in HB Ag titer in 12 days to 4 times the pretreatment level, an increase in SGOT within 20 days to 250 IU/liter, and an increase in SGPT within 20 days to 320 IU/liter. Thereafter, the transaminases returned to normal and the HB Ag decreased to 50% of the pretreatment level. In contrast, subsequent treatment of this patient with transfer factor prepared from 1.5 x 10^9 lymphocytes from the same donor had no effect. In the third patient, 4-month-old female infant whose mother had acute hepatitis B, administration of transfer factor prepared from 4.7 x 10^9 lymphocytes obtained from the mother caused transient increases in serum HB Ag, SGOT, and SGPT. A second treatment of the infant with transfer factor from 5 x 10^8 lymphocytes caused a repetition of the transient responses, followed by a gradual decrease in HB Ag titer, prolonged increases in SGOT and SGPT, and eventual reduction of HB Ag titer by 95% and normalization of SGOT and SGPT activities. Adoptive transfer of humoral immunity does not, therefore, appear to modify established hepatitis B infection, whereas adoptive transfer of cell-mediated immunity does. It is postulated that liver cell injury in hepatitis B may be related more to the host's cell-mediated immune response than to a cytopathogenic effect of the putative hepatitis B virus.

6388 TRIALS OF IMMUNOSUPPRESSIVE TREATMENT FOR PROTRACTED HEPATITIS IN SMALL CHILDREN.

(Pol.) Rabenda, C.; Pradota, A.; Rudkowski, Z. (Med. Acad. Wroclaw, Poland). *Pediatr. Pol.* 48(3):351-356, 1973.

Immunosuppressants were used to obtain complete remissions of protracted hepatitis in 2 children with marked hepatosplenomegaly, jaundice, and elevated SGOT, SGPT, and bilirubin levels which failed to respond to corticosteroids. A 3-month-old-infant was first treated unsuccessfully for 6 weeks with prednisone (dose not specified). During the 4th month, cyclophosphamide was administered for 4 weeks, first at a dose of 1.8 mg/kg/day and then at 0.9 mg/kg/day. A full clinical and biochemical remission was achieved 10 weeks after initiation of immunosuppressive therapy (6 weeks after discontinuation of the drug). The second patient, a 27-month-old child, had brief, incomplete remissions when treated with prednisone (dose not specified), but these became less pronounced and of shorter duration. After 8 months of prednisone therapy, cyclosphosphamide was administered at a dose of 0.7 mg/kg/day. This was followed by azathioprine (0.8 mg/kg/day) combined with prednisone (dose not specified). Immunosuppressive therapy was continued for 6 months. A complete remission occurred 8 months after initiation of this therapy, 2 months after discontinuation of treatment. Both children are well 1 yr later.

6389 HUMORAL IMMUNITY IN CHRONIC LIVER DISEASE.

(E.) Simon, K.; Patakfalvi, A.; Par, A. Miszlay, Zs. (Univ. Med. Sch., Pecs, Hungary). *Acta Med. Acad. Sci. Hung.* 30(4):283-292, 1973.

To investigate possible diagnostic aids for various types of chronic liver disease, the humoral immune response was studied in 69 patients who had chronic active hepatitis (20), chronic persistent hepatitis (13), cirrhosis (23), and fatty liver (13). Tests used for serum protein changes were γ-globulin level, erythrocyte sedimentation rate, and thymol turbidity. Hyperfunction in these tests was most typical in chronic active hepatitis and least typical in fatty liver, but this was not always valid for individual cases. Changes in serum IgA, IgG, and IgM levels, regarded as characteristic for individual categories of chronic liver disease, could not be used to establish a diagnosis in individual cases. Antibody titers to *Salmonella*, *Staphylococcus*-α, *Shigella*, and *Escherichia coli* did not appear to reflect variations in serum immunoglobulin levels. However, antibodies to enteric bacteria (*Salmonella*, *Shigella*, and *E. coli*) were more valid indicators of enhanced immune activity that those to nonenteric bacteria (*Staph.*-α). The most consistent rise in enteric antibody titer was found in chronic persistent hepatitis. The final parameter studied was the level of autoantibody serum factors (rheumatoid, lupus erythematosus, and antinuclear and/or anticytoplasm factors together with complement-fixing antibodies to subcellular fractions). Immunofluorescence tests for antinuclear and/or anticytoplasmic factors, together with complement-fixation tests with subcellular fractions, were quite specific for chronic active hepatitis, giving positive results in 18 of 20 cases. Both these tests were completely negative, however, in patients with fatty liver, and the complement-fixation test was also negative in patients with chronic persistent hepatitis. The tests for rheumatoid factor were far less specific than the immunofluorescence and complement-fixation tests for chronic active hepatitis. The presence of these autoantibodies suggest probable involvement of autoimmune mechanisms in chronic liver disease.

6390 PRELIMINARY RESULTS FROM TREATING CHRONIC AGGRESSIVE HEPATITIS WITH D-PENICILLAMINE (CUPRENIL "POLFA"). *(Pol.)* Eisner, M.; Goertz, J.; Dobrohorska, H.; Bohdanowicz, I. (Pomeranian Acad. Med., Szczecin, Poland). *Pol. Tyg. Lek.* 28(44):1721-1724, 1973.

Good results were obtained by treating 5 patients (2 men and 3 women, aged 31-67 yr) with 9-43 month histories of chronic aggressive hepatitis for 6-12 months with d-penicillamine. The drug was administered in increasing dosages until 1000-1500 U/day were reached. All patients received vitamin B_6 and 1 was given prednisone in decreasing amounts (30-5 mg/day). Four of the 5 had previously been treated with prednisone alone or with prednisone and azathioprine and had developed steroid diabetes. Full or partial clinical remissions were achieved which lasted 3-18 months after discontinuation of treatment. Jaundice, fever, hepatosplenomegaly, and hemorrhagic diathesis disappeared, and biochemical parameters (bilirubin, SGPT, alkaline phosphatase, proteinogram, plasma unstable colloids, and iron) were completely or partially normalized in all patients. Follow-up liver biopsies performed on 3 patients 8, 10, and 15 months after treatment revealed a marked decrease in inflammation and no progression of necrosis. Steroid diabetes disappeared. With the exception of 1 patient who developed allergic dermatitis, forcing discontinuation of treatment after 8 months, d-penicillamine was well tolerated.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

6396 ELECTRON MICROSCOPE STUDY OF MECHANISMS BY WHICH HEPATIC LIPIDS ARE DEPOSITED AND DISAPPEAR IN ALCOHOLIC STEATOSIS. *(Fr.)* Tanikawa, K.; Miyakoda, U. (Med. Sch., Univ. Kurume, Japan). *Ann. Gastroenterol. Hepatol. (Paris)* 9(5):411-422, 1973.

Electron microscope examinations were made of material biopsied from the livers of 5 patients with alcoholic steatosis shortly after their admission to the hospital and 1-2 weeks after they had been placed on a high-protein diet and had abstained from alcohol. Blood samples were collected at the same times to analyze the blood lipid composition and to perform liver function tests. Initially large lipid droplets were found in almost all of the liver cells. The most pronounced ultrastructural change was marked dilatation of cisternae in the rough endoplasmic recticulum. This appeared to be the initial stage in the accumulation of lipids in the liver. Membranous structures appeared along the edges of fat droplets as large fat droplets developed rapidly by fusion of small fat inclusions. Giant mitochondria and iron deposits were common, and the cytoplasm of fat storage cells, ordinarily found in Disse's spaces, contained an increased number of fat droplets. As liver cells returned to normal, many vesicles containing osmophilic particles, probably lipoproteins, were observed in the endoplasmic reticulum. Proliferation of the Golgi apparatus was associated with increases in the levels of the serum triglycerides and pre-β-lipoproteins. This suggests that trigylcerides which had been deposited in the liver are actively liberated into the blood during regression of fatty liver.

6397 ALPHA-1-FETOPROTEIN AND ALCOHOLIC HEPATITIS. *(E.)* Meshkinpour, H.; Wepsic, H. T.; Schmalhorst, W. R. (Kern Gen. Hosp., Bakersfield, Calif.). *Am. J. Dig. Dis.* 19(8):709-713, 1974.

A chronic alcoholic male, aged 41 yr, was admitted for progressive nausea, vomiting, weakness, and increased abdominal girth. He was deeply jaundiced and slightly edematous, but there was no evidence of portosystemic encephalopathy. The SGOT value was 210; alkaline phosphatase, 310 mIU/ml; and hepatitis-associated antigen, negative. On the 2nd, 3rd, and 5th hospital days, serum α_1-fetoprotein, determined by quantitative electroimmunodiffusion, was reported as 25, 30 and 50 µg/ml, resp., compared to the value of 0.06 µg/ml for the upper normal limit. A 4th blood sample on the 18th hospital day was studied by radioimmunoassayand revealed an α_1-fetoprotein value of 0.35 µg/ml. After the patient's death in hepatorenal syndrome on the 22nd hospital day, autopsy revealed no gross evidence of hepatic tumor. Microscopic examination showed an overall picture of Laennec's cirrhosis with superimposed alcoholic hepatitis. No evidence of malignancy was seen in other organs. Based on previous evidence of production of α_1-fetoprotein following hepatocyte proliferation *in vivo* or *in vitro*, it is speculated that the transient elevation of serum α_1-fetoprotein in this patient was caused by a population of dividing hepatocytes. This case clearly demonstrates that elevated serum α_1-fetoprotein may be seen in alcoholic liver disease in the absence of any neoplastic disease. It is proposed that monitoring the rate of increase in α_1-fetoprotein concentration may be helpful in differentiating hepatocellular carcinoma, for which elevations over a short period are to be expected, from liver regeneration secondary to alcoholic or viral hepatitis, for which only a transient elevation is to be expected with a return to normal levels as liver regeneration subsides.

6398 ABSORPTION OF HEMOGLOBIN AND HEMOGLOBIN IRON IN ALCOHOL-INDUCED LIVER INJURY. *(E.)* Bungert, H. J. (Steglitz Clin., Free Univ. Berlin, Germany). *Digestion* 9(4):293-308, 1973.

Experiments were conducted to determine if hemoglobin could be absorbed as a complete molecule in Sprague-Dawley rats with liver injury induced by p. o. administration of 39.34% ethanol (7 g/kg/day) through a stomach tube for 3 weeks. The injury consisted of fatty metamorphosis with focal hepatocellular degeneration and round cells. Unlabeled human hemoglobin (500 mg/kg) prepared from crude red cell sediment, was administered p. o. through a stomach tube to rats with liver injury, pair-fed normal rats, and anemic rats (bled 5 ml for 4 days); all rats were fed a diet containing 18 mg iron/1000 g diet and 19% protein. Comparison was also made between iron absorption in iron-deficient, alcohol-fed, normal, and iron-loaded rats given labeled hemoglobin-iron (100 µg p.o. through a stomach tube). Immunoelectrophoresis and gel filtration studies showed no absorbed hemoglobin in healthy or anemic rats. Animals with alcohol-induced liver injury absorbed 15% of the administered iron. The serum iron content was significantly higher in these animals, indicating a two-step mechanism for iron absorption. Serum heme iron was also enhanced, as was total liver iron. Alcohol-fed animals were not anemic. Immunofluorescent investigations showed yellow-green fluorescent duodenal cells 90 min after hemoglobin and hemoglobin-haptoglobin administration to rats; anti-hemoglobin (crude and purified) antibodies complexed with fluorescein isothiocyanate. The same fluorescent cells were benzidine-positive. On polyacrylamide gels, hemoglobin-haptoglobin and free heme in liver homogenates could be detected with the benzidine reaction. These results indicate that hemoglobin is absorbed and transported to the liver as a hemoglobin-haptoglobin complex in rats with ethanol-induced liver injury. It is noted that iron, split from hemoglobin in the lumen, is absorbed in the 1st phase of iron absorption. At the same time, ferritin is produced in small quantities. In the 2nd phase, iron split from hemoglobin in mucosal cells and hemoglobin itself are transported to the portal blood. Of the 2 iron-binding proteins involved in hemoglobin absorption, one is ferritin and the other a protein similar to transferrin. The latter could be haptoglobin or a hemoglobin-haptoglobin complex.

LIVER AND BILIARY TRACT

Cirrhosis

6399 THERAPEUTIC PORTACAVAL SHUNT: PRELIMINARY DATA ON CONTROLLED TRIAL AND MORBID EFFECTS OF ACUTE HYALINE NECROSIS. *(E.)* Mikkelson, W. P. (Univ. Southern California Sch. Med., Los Angeles). *Arch. Surg.* 108(3):302-305, 1974.

A controlled study of end-to-side portacaval shunt as a therapeutic measure for treatment of patients having liver cirrhosis associated with alcoholism was carried out. Thirty four patients in one randomized group were operated upon; 35 in another group were given medical treatment. The shunted patients showed a five-year survival rate of 60%; the medically treated patients, 10%. There were twice as many deaths in the medically treated group as in the group operated upon (18 *vs* 9). Recurrent encephalopathy occurred in 7 of the shunted patients, 2 of whom were among those who died, while none of the medically treated patients developed the syndrome. Moderate to severe degrees of acute hyaline necrosis adversely affected the survival after portacaval shunt, indicating the need for liver biopsy preceeding consideration of the operation.

6400 INVESTIGATIONS ON PLASMA VISCOSITY IN PATIENTS WITH CIRRHOSIS OF THE LIVER. *(E.)* Leonhardt, H.; Bungert, H. J. (Free Univ., Berlin, Germany). *Acta Hepatogastroenterol.* 21(2):127-130, 1974.

In studies carried out on 29 patients with cirrhosis of the liver and on 26 healthy subjects matched for age and sex, it was demonstrated that the mean plasma viscosity for the former group was significantly higher than that for the latter. The viscosity showed a positive correlation with total protein, gamma-globulin, and fibrinogen. The raised gamma-globulins in patients with cirrhosis of the liver were principally responsible for the higher plasma viscosity.

6401 BLOOD AMMONIA LEVELS IN ADVANCED CIRRHOSIS DURING THERAPEUTIC ELEVATION OF THE INSULIN:GLUCAGON RATIO. *(E.)* Walker, C.; Peterson, W.; Unger, R. (Univ. Texas Health Sci. Ctr., Dallas). *N. Engl. J. Med.* 291(4):168-171, 1974.

To determine whether inhibition of hepatic ureagenesis by increased insulin secretion or decreased glucagon secretion might reduce ammonia formation, a group of 5 patients with advanced cirrhosis was administered an oral glucose dietary supplement. Oral glucose supplementation was used as a device for augmenting insulin secretion and reducing glucagon secretion. Hepatic ureagenesis was viewed as a byproduct of gluconeogenesis from amino acids and was expected to be inhibited by insulin and augmented by glucagon. Urea, in turn, was expected to be converted to ammonia by urea-splitting bacteria in the large bowel. The patients selected for the study showed a consistent basal and post-prandial hyperammonemia while on a diet containing 40-60 g/day protein. Each patient was subjected to 4 separate 9-hr studies in 2 of which the diet was supplemented hourly with 20 g oral glucose. Plasma insulin and glucagon and blood ammonia were measured at frequent intervals. Without glucose supplementation, mean blood ammonia rose 20 μg/100 ml, insulin averaged greater than 50 μU/ml, and glucagon averaged greater than 160 pg/ml. With glucose supplementation, mean insulin rose to 201 μU/ml and glucagon fell below basal values, while blood ammonia did not rise, but declined significantly. A causal connection was suggested between the rise in the insulin:glucagon ratio and the decline in blood ammonia. The explanation was offered that the high insulin:glucagon ratio may have reduced the blood ammonia after a protein meal by decreasing hepatic ureagenesis directly, or indirectly through a reduction in amino acid availability for gluconeogensis, or both. Reduction in amino acid availability for gluconeogenesis might result from the action of insulin in increasing amino acid incorporation into protein.

6402 PREDICTORS OF SURGICAL MORTALITY IN PATIENTS WITH CIRRHOSIS AND NONVARICEAL GASTRODUODENAL BLEEDING. *(E.)* Wirthlin, L. S.; van Urk, H.; Malt, R. B.; Malt, R. A. (Massachusetts Gen. Hosp., Boston). *Surg. Gynecol. Obstet.* 139(1): 65-68, 1974.

Records of 63 cirrhotic patients were analyzed for determinants of mortality after operations for emergency control of nonvariceal upper gastrointestinal bleeding. The aggregate mortality rate was 57%, where mortality was defined as death during hospitalization or within 6 weeks of operation. Causes of bleeding were chiefly peptic ulceration and gastritis. Experience of the surgeon, choice of operation, and duration of operation were not significant predictors of death. Although the serum bilirubin level taken just before surgery was the best single predictor of death for grouped data, a more accurate estimate for an individual patient could be derived from an empiric five point score, where one point is assigned for presence of each of the following signs or tests: serum bilirubin level over 2 mg/dl, serum albumin level less than 3 g/dl, prothrobin time over 16 sec, presence of encephalopathy, and presence or history of varices. The total predicts mortality with near linearity. A score of even 1 point is associated with a 43% mortality rate; 3 points, with 85% rate; 4 points, with invariable death. For most cirrhotic patients bleeding from peptic ulcer or gastritis, attempts at controlling the hemorrhage with selective intra-arterial infusion of vasopressin seemed preferable to an emergency operation on the stomach or duodenum.

6403 PREOPERATIVE PARAMETERS INFLUENCING SURVIVAL IN PATIENTS WITH ELECTIVE PORTACAVAL SHUNTS. *(E.)* Maillard, J. N.; Clot, P.; Coste, T. (Beaujon Hosp., Clichy, France). *Digestion* 10:129-137, 1974.

In 145 patients submitted to elective portacaval anastomosis for intrahepatic block and followed up for periods ranging from 1 to 9 years, long-term survival was analyzed in its relation to the 4 classical preoperative parameters: age, liver size, hepatic histology, and hepatic function. The range in age was from 20 to over 60 yr. Liver size was determined by preoperative splenoportography and was confirmed at operation. Hepatic histology was evaluated on the basis of fibrosis, inflammatory change, and cell changes. Hepatic function was based on plasma fibrinogen, Factor VII, Factor X, serum albumin, serum bilirubin, and BSP clearance. The findings showed no relation between age at time of operation and mortality. Patients whose livers were of normal size survived longer than those whose livers were atrophic or hypertrophic, but there was no difference in survival between the groups with atrophic and hypertrophic livers. Histological change and impairment of hepatic function were related to mortality in the first post-operative year only. This last finding might be attributed to the selection effected during the first year, which is more sparing of those with moderate than of those with severe pathological changes; to the fact that the subjects with the most advanced cirrhosis are the least exposed to work accidents or to the consequences of arterial atheroma; or to the need of the liver of about a year to adapt itself to the new hemodynamic conditions imposed by a portal-systemic shunt.

6404 HIGH PROTEIN ASCITES IN PATIENTS WITH UNCOMPLICATED HEPATIC CIRRHOSIS. *(E.)* Sampliner, R. E.; Iber, F. L. (VA Hosp., Baltimore, Md.). *Am. J. Med. Sci.* 267(5):275-279, 1974.

Ascitic fluid protein concentrations of greater than

2.5% in cirrhosis are usually interpreted as evidence of superimposed neoplastic, infectious, or other inflammatory processes. To test the validity of this arbitrary criterion, hospital laboratory records were examined for level of ascitic fluid protein in uncomplicated cirrhosis. Twenty-one such patients were found, having ascitic fluid protein levels ranging from 2.6 to 4.1%. To determine the frequency of high protein ascites, 98 consecutive hospital admissions with uncomplicated cirrhosis and ascites were reviewed. Nineteen had ascitic fluid protein greater than 2.5% and 12 a protein concentration greater than 3.0%. The ascites fluid protein ranged from 0.1 to 4.3%, with a mean of 1.5%. Thus, high protein ascites is more common in uncomplicated cirrhosis than had been recognized.

6405 HYPERGLUCAGONEMIA IN LAENNEC'S CIRRHOSIS: THE ROLE OF PORTAL-SYSTEMIC SHUNTING. *(E.)*

Sherwin, R.; Joshi, P.; Hendler, R.; Felig, P.; Conn, H. O. (Yale Univ. Sch. Med., New Haven, Conn.). *N. Engl. J. Med.* 290(5):239-242, 1974.

Plasma pancreatic glucagon concentrations in 18 men (aged 35-7 yr) with Laennec's cirrhosis were determined in the basal state and after alanine infusion (0.15 g/kg for 2-5 min). For the entire group of patients, basal glucagon concentrations were 3 times greater than in 11 control subjects, while the glucagon response to alanine was 3 to 13 times greater. Glucagon levels were highest in 4 patients with portacaval anastomosis, less elevated in 10 with spontaneous portal-systemic shunting, and normal in 4 without portal-systemic shunting. In all 3 groups glucagon concentrations correlated closely with the degree of ammonia intolerance. Elevations of plasma tyrosine, methionine, and phenylalanine were observed in the cirrhotic group, whereas the levels of branched-chain amino acids (valine, leucine, and isoleucine) were reduced. Hyperglucagonemia may contribute to the glucose intolerance observed in cirrhosis.

6406 ANTIBODIES TO HUMAN ALBUMIN IN CIRRHOTIC SERA. *(E.)*

Hauptman, S.; Tomasi, T. B. (Mayo Fdn., Rochester, Minn.). *J. Clin. Invest.* 54(1): 122-127, 1974.

Antibody-like activity against altered human albumin was demonstrated in 7 of 18 (40%) sera from patients with Laennec's cirrhosis. Agglutinating activity toward sheep RBC coated with aggregated albumin was present in the void volume on Sephadex G-200 chromatography and was shown to be due to an immunoglobulin by its removal on passage over an anti-L-chain immunoadsorbent column. IgA was isolated from cirrhotic sera by acid elution from an aggregated albumin immunoadsorbent column. Complex formation between albumin and the IgA was demonstrated by absorption of the IgA and of a ^{125}I-labeled fragment with antigen-binding activity (Fabx) derived from it on aggregated albumin columns. The specificity of cirrhotic IgA for altered albumin was also shown by facilitated hemagglutinatation of sheep RBC coated with aggregated albumin. In control tests, normal and myeloma IgA and myeloma Fabx fragments showed no evidence of complex formation with albumin. Restriction of the antibody response to the IgA class may result from the formation of antibodies against albumin altered during metabolism in the gastrointestinal tract. With regard to the possible biological effects of antialbumin antibodies, it is suggested that such antibodies alter the synthesis and/or catabolism of albumin. It is also suggested that immune complexes containing altered albumin, or the development of delayed hypersensitivity to albumin, might perpetuate liver damage induced by alcohol.

6407 MITOCHONDRIAL ANTIBODIES IN EXTRAHEPATIC BILIARY OBSTRUCTION. *(E.)*

Richer, G.; Viallet, A. (Saint-Luc Hosp., Montreal, Canada). *Am. J. Dig. Dis.* 19(8):740-744, 1974.

To re-examine the question of whether the presumably specific serum mitochondrial antibody test for primary biliary cirrhosis would exclude extrahepatic biliary obstruction, 732 patients were divided into 7 groups according to their diagnosis and their sera were examined for the presence of antimitochondrial antibody by indirect immunofluorescence using rat kidney sections. While 5 of 5 patients with primary biliary cirrhosis, 3 of 25 with chronic hepatitis, and 1 of 159 with alcoholic liver disease gave a positive test, all 36 patients with extrahepatic biliary obstruction, 100 with viral hepatitis, 56 with other liver diseases, and 351 without known liver disease gave a negative test. Of the patients with extra-hepatic biliary obstruction, 14 had histories of obstruction dating back more than 3 months. It is concluded that the presence of mitochondrial antibodies in serum remains a useful diagnostic tool in the differential diagnosis between primary biliary cirrhosis and extrahepatic biliary construction.

6408 BILE ACIDS IN HEPATIC BILE IN LIVER DISEASE. *(E.)*

Kuroda, T.; Okuda, K. (Chiba Univ. Sch. Med., Japan). *Acta Hepatogastroenterol.* 21(2): 120-126, 1974.

Bile acids in hepatic bile of patients with various liver disorders were analyzed by thin-layer chromatography. Samples were collected through a duodenal tube from 50 patients, aged 15-66 yr, with mild to moderately severe acute hepatitis (22), chronic aggressive hepatitis (5), cirrhosis of the posthepatitic type (12), cholelithiasis with stones in the bladder, probably of the cholesterol type (4), and external biliary drainage (9) of whom 6 had had cholecystectomy for stones and 3 resection of the pancreas head and had a Nealton type catheter in the common duct. Deoxycholic acid was markedly decreased relative to cholic acid and chenodeoxycholic acid in patients with external bile fistula and acute hepatitis, and to a lesser extent in liver cirrhosis and chronic hepatitis. The glycocholate/taurocholate ratio was decreased in acute hepatitis but was increased remarkably in fistula bile. The clinical significance of the observed decreases of deoxycholate and glycine/taurine ratio in liver diseases has yet to be clarified.

6409 COMPARATIVE STUDY OF LACTULOSE AND NEOMYCIN IN THE TREATMENT OF PORTOSYSTEMIC ENCEPHALOPATHY. *(Sp.)* Sala Felis, T.; Berenguer, J.; Barrios, J. M.; Gomez, J. (La Fe Munic. Sanit., Valencia, Spain). *Rev. Esp. Enferm. Apar. Dig.* 42(3):335-342, 1974.

Alternate 14-day courses of lactulose (90 ml/day p. o. divided into 3 doses) and neomycin (3 g/day p.o. divided into 3 doses) were administered to 12 patients (5 men and 7 women) with portosystemic encephalopathy. Initially these patients were fed a diet containing 40-60 g/day protein. After 7 days the dietary protein intake was increased to 100 g/day and the same medication was continued for another 7 days. During the 3rd week medication was discontinued and patients were allowed to eat what they wanted. During weeks 4 and 5, patients initially given neomycin received lactulose and *vice versa*. No significant differences were found between the effects of neomycin and lactulose on clinical symptoms (somnolence, flapping tremor, fetor hepaticus) or blood ammonia levels. Lactulose never produced deteriorations in the electroencephalogram. In 5 cases lactulose caused more improvement in the electroencephalogram than neomycin, while in 7 cases results obtained with lactulose and neomycin were comparable. Increased dietary protein intake was tolerated better with lactulose in 5 cases and with neomycin in 2; in 5 other cases the results with both drugs were similar. Lactulose, although it had to be discontinued in 1 case, produced fewer side effects than neomycin: 10 patients tolerated lactulose well and 2 developed pronounced flatulence, borborygmus, diarrhea, and a distaste for the drug. Neomycin produced epigastric pain, nausea, pyrosis, and constipation in 6 patients. From these findings and others in the literature, it is concluded that lactulose is a very useful drug for the treatment of portosystemic encephalopathy.

6410 SPONTANEOUS PERITONITIS IN CIRRHOTIC ASCITES. *(E.)* Curry, N.; McCallum, R. W.; Guth, P. H. (Wadsworth VA Hosp., Los Angeles, Calif.). *Am. J. Dig. Dis.* 19(8):685-692, 1974.

Spontaneous bacterial peritonitis was identified in a 10-yr retrospective study of 15 patients (14 males and 1 female, aged 33-62), with cirrhosis and ascites. Laennec's cirrhosis was diagnosed in 13 patients and chronic active hepatitis with postnecrotic cirrhosis in 2. All patients had abdominal pain prior to diagnosis, fever was present in 11 (73%), increasing hepatic encephalopathy in 5 (33%), unexplained shock in 3 (20%), and esophageal variceal bleeding in 2 (13%). Diagnosis was established by paracentesis with the finding of either an elevated ascitic fluid cell count (>300 WBC/mm^3) in 13 cases or organisms and numerous neutrophiles on gram stain in 6 cases. *Escherichia coli* was the most common organism and was isolated from 6 patients on ascitic fluid culture. *Klebsiella* was isolated in 3, and *Diplococcus pneumoniae* in 2 cases. Positive blood cultures were obtained in 60% of the patients. Therapy, including antibiotics, was successful in 3 patients who survived to leave the hospital. Neither delay in diagnosis nor severity of liver disease were of value in separating survivors from nonsurvivors. Nonsurvivors died from complications of advanced liver disease such as hepatic coma, hepatorenal syndrome, and esophageal variceal bleeding. It is concluded that spontaneous peritonitis is a diagnosable and possibly treatable cause of deterioration in the cirrhotic patient. Due to its varied presentation it may escape recognition.

6411 INTERMITTENT IDIOPATHIC PORTAL HYPERTENSION. *(E.)* Mendenhall, C. L.; Sherman, J.; Chedid, A. (VA Hosp., Cincinnati, Ohio). *Gastroenterology* 67(1):142-148, 1974.

A 46-year-old patient with idiopathic portal hypertension for which the initial symptoms were nausea and vomiting of blood developed a series of exacerbations and remissions as documented by clinical, laboratory, and manometric studies over an 18-month observation period. The liver pathology was initially normal, but gradually deteriorated as revealed in the portal areas by venous dilation, increased prominence and density of collagenous tissue, and thickening of the arterial muscularis. Hepatic vein wedge pressure was elevated at 272 mm saline. Hepatic blood flow was 642 ml/min, compared to normal values of 1000-1500 ml/min. Liver function tests were otherwise essentially normal. Esophagoscopy at times of remission revealed varices. Splenomegaly also appeared intermittently and the splenic pulp pressure was found on different occasions to be 238 and 258 mm saline. Treatment with oral guanethidine, 10 mg/day at first, 25 or 30 mg/day later, resulted in a rapid fall in splenic pulp pressure to within normal limits of 122 to 162 mm saline and a decrease in splenic size. A splenorenal shunt operation was eventually performed, and reevaluation of the patient 1 yr later showed no evidence of esophageal varices or abnormal liver function, but pathological examination of the liver indicated slowly progressive periportal fibrosis. Special interest in this patient had to do with the appearance of esophageal varices without initial evidence of portal obstruction or hepatic cirrhosis, a portal vein wedge pressure less than the splenic pulp pressure, and the intermittent character of the portal hypertension and the splenomegaly. The data are considered to be consistent with a vasospastic process resulting from either a circulating or fixed tissue substance which affects both sinusoidal and portal vasculature so as to produce a combined para- and presinusoidal hypertension with a decreased total hepatic blood flow.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

6419 GALLSTONE DISSOLUTION IN VITRO BY BILE ACIDS, HEPARIN, AND QUATERNARY AMINES. *(E.)* Lahana, D. A.; Bonorris, G. G.; Schoenfield, L. J. (Cedars-Sinai Med. Ctr., Los Angeles, Calif.). *Surg. Gynecol. Obstet.* 138(5):683-685, 1974. 138(5):683-685, 1974.

Cholesterol gallstones from 3 patients were immersed in solutions of bile salts, heparin, hexamethonium, and/or cetylpyridinium. Of the three bile salts tested sodium cholate dissolved 44% of the total weight of the stone, as compared with a 26% dissolution with chenodeoxycholate and 14% with deoxycholate. The decrease in stone weights were accounted for by the dissolved cholesterol in the bathing solutions. Heparin dissolved 20 to 41% of the stone by fragmentation, the degree of fragmentation being dependent on the concentration of heparin. Hexamethonium achieved an 8% fragmentation, while cetylpyridinium produced a 40% fragmentation. In heparin mixed with sodium cholate, 51-57% of the stones dissolved, the degree of dissolution being dependent on the heparin concentration. In addition, the rate of dissolution remained the same for 7 days with the mixed solution, while it diminished with either heparin or cholate alone. Stone dissolution was not increased by other combinations of bile acids, surface-active agents, and heparin. After appropriate safety testing in animals, these agents should be studied further as T-tube infusates for the dissolution of retained duct stones.

6420 URINARY FLUORESCENCE IN PATIENTS WITH JAUNDICE. *(Rus.)* Starosel'skii, D. V.; Ul'ianov, A. P. (Crimean Med. Inst., Simferopol, USSR). *Lab. Delo* (11):653-655, 1973.

After precipitation of bile pigments with lead acetate, the intensity of fluorescence and fluorescence spectra were measured on dilute 24-hr urine specimens from 40 patients with hepatitis, 4 with obstructive jaundice, and 4 normal controls. Fluorescence was also studied visually on urine from 120 patients with viral hepatitis, 11 with obstructive jaundice resulting from pancreatic carcinoma, and 10 normal controls. In most cases, the intensity of fluorescence was greater in urine from hepatitis patients than in normal urine. Fluorescence was most intense at the onset and decreased with recovery in patients with mild hepatitis while the reverse was true of those with severe hepatitis. The method of treatment employed had no effect on urinary fluorescence. The intensity of urinary fluorescence increased as the disease progressed in patients with obstructive jaundice. Fluorescence spectra revealed that increased fluorescence observed in 2/3 of the patients with hepatitis was due to increases in bands with maxima at 460 and 516 nm. Only the band at 516 nm was visible in patients with obstructive jaundice and at the onset of symptoms in 1/3 of those with hepatitis. These findings indicate that changes in fluorescence which occur in patients with jaundice are not due to the presence of bile pigments or to unusual fluorescent products, but to the presence of substances which extinguish the shortwave part of the fluorescence spectrum, thereby changing the color of the fluorescence. Although examination of urinary fluorescence would appear to be of no value in the differential diagnosis of jaundice, an early increase in the intensity of fluorescence and a change in its color could serve as one of the signs for diagnosing mild or subclinical forms of viral hepatitis. However, the effect of other diseases and drugs (none of which are used to treat viral hepatitis) must be taken into consideration.

6421 CHOLANGIOMETRY PERFORMED DURING SURGERY: RESULTS OF 375 DETERMINATIONS. *(Sp.)*

Romano, S. (Ciudadela Polyclin., Buenos Aires, Argentina). *Rev. Esp. Enferm. Apar. Dig.* 42(2):155-164, 1974.

Measurements of residual pressure and flow were performed on 375 patients during surgery on the extrahepatic biliary tract. Patients undergoing emergency surgery and those with jaundice or gross evidence of tumors were excluded. Anesthetics and drugs interfering with function of the duodenal muscle and sphincter of Oddi were avoided. After catheterization of the cystic duct with a metal sound, the residual pressure was measured with a Becton Dickinson water manometer and flow was investigated by perfusing a saline solution through at 37 C. In 317 cases the flow of saline was greater than 12 ml and the residual pressure was less than 15 cm H_2O, indicating that no obstructions were present. Flows of less than 12 ml and residual pressures higher than 15 cm H_2O, present in 40 patients, suggested that obstructions were present in the common bile duct or at the choledochoduodenal junction; only 1 false-positive result was obtained in this group. The 39 patients with confirmed obstructions consisted of 27 with choledocholithiasis, 6 with choledocholithiasis and stenosis of the sphincter of Oddi, 5 with stenosis of the sphincter of Oddi, and 1 with stenosing pancreatitis. Of 6 patients with residual pressures of less than 15 cm H_2O and flows greater than 12 ml, 2 had gallbladder disease associated with choledocholithiasis. Pressures less than 15 cm H_2O and flows of less than 12 ml, found in 7 patients, were probably due to partial obstructions which made it possible for the pressure to slowly stabilize at normal values but decreased the flow. Thus, false-positive results were obtained in only 12 (2.5%) of the 375 patients examined.

6422 PIGMENT vs CHOLESTEROL CHOLELITHIASIS: COMPARISON OF STONE AND BILE COMPOSITION. *(E.)*

Trotman, B. W.; Ostrow, J. D.; Soloway, R. D. (Hosp. Univ. Pennsylvania, Philadelphia). *Am. J. Dig. Dis.* 19(7):585-590, 1974.

A comparative study of gallstone and gallbladder bile composition was made using 100 unselected American patients, 23 with pigment and 77 with cholesterol cholelithiasis. Cholesterol stones were composed of an unidentified residue, bilirubin, and bile salts. The residue in pigment stones was not calcium bilirubinate, which sharply contrasts with the composition of bile pigment calcium stones found in Japanese subjects. Bile composition of the two groups differed in that the cholesterol content of biles surrounding pigment stones was significantly less than that of biles surrounding cholesterol stones. Bilirubin in biles was conjugated, but the pigment extracted from stones was unconjugated bilirubin. The data suggest that conjugated bilirubin is hydrolyzed during or after stone formation.

6423 ABNORMAL COMMUNICATION BETWEEN THE GASTROINTESTINAL AND BILIARY TRACTS. (BILIODIGESTIVE FISTULAS AND INCOMPETENCE OF THE SPHINCTER OF ODDI.

(Sp.) Perez Jimenez, F.; Muros, J.; Hitos, E. (La Paz Munic. Sanit., Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 39(2):129-142, 1973.

Case reports are presented for 7 patients with biliodigestive fistulas, 2 with malfunction of the sphincter of Oddi, and 2 whose problems were not definitely diagnosed. Of 3 patients with surgical fistulas, 2 had undergone choledochoduodenostomy for jaundice which developed after cholecystectomy and for a benign stricture of the common bile duct, resp., and 1 had undergone cholecystojejunostomy for a malignant neoplasm in the head of the pancreas. Although i.v. cholangiography, performed on 2 of these patients, did not visualize the biliary tract, a barium meal did. One patient with a choledochoduodenostomy remained asymptomatic for 20 yr before developing esophageal varices and symptoms of cirrhosis. Malfunction of the sphincter of Oddi, diagnosed in 2 patients resulted from a surgical papillotomy in one and probably from a calculus which damaged the sphincter before passing into the duodenum in the other. Simple abdominal radiography demonstrated aerobilia in both cases; the cause of the aerobilia was established only at surgery in one patient, but was evident from a barium meal in the other. Of the 4 patients with spontaneous fistulas, 1 had a choledochoduodenal fistula, 2 had cholecystoduodenal fistulas, and 1 had a cholecystogastric fistula. The fistulas were definitely caused by calculi in 2 cases; in another case calculi were probably involved, while in the remaining patient either calculi or an old duodenal ulcer could account for the fistula. A barium meal passed into the biliary tract in 3 of these 4 patients, while a calculus was found in the duodenum of the 4th, suggesting the presence of a fistula. Radiological findings were suggestive of a duodenobiliary fistula in 1 case, but this could not be confirmed at surgery. In another case aerobilia and cholecystolithiasis were demonstrated radiologically but the patient refused surgery.

6424 ROLE OF GALLBLADDER IN GALLSTONE FORMATION.

(E.) Nakayama, F.; van der Linden, W. (Kyushu Univ. Fac. Health Sci., Fukuoka, Japan). *Acta Chir. Scand.* 139(1):45-49, 1974.

Bile composition before and after cholecystectomy was compared in cholelithiasis patients to assess the role of the gallbladder and to study the effect of cholecystectomy on hepatic bile. Most hepatic bile obtaine at laparotomy was oversaturated with cholesterol. Most gallbladder bile was not. The first finding is likely due to functional interruption of the enterohepatic circulation of bile salts during overnight fast prior to operation. After cholecystectomy and reestablishment of the enterohepatic circulation, hepatic bile was stabilized in terms of cholesterol solubility. This agrees with the fact that recurrence of cholesterol gallstones is seldom seen after cholecystectomy and stresses the importance of the gallbladder in the formation of gallstones. After cholecystectomy and reestablishment of the enterohepatic circulation, hepatic bile contained less deoxycholic acid than before. This indicates a more efficient enterohepatic circulation with less bile salt spillover into the colon. This gain in efficiency may compensate for diminished bile salt pool size, and the bile salt level in bile can be held sufficiently high for the solubilization of cholesterol. Thus, in the absence of a gallbladder, a diminished bile acid pool size does not necessarily lead to cholesterol supersaturation and gallstone formation.

GENERAL

6462 STUDIES WITH TWO GASTRIN ANTISERA OF DIFFERENT SPECIFICITY FOR GASTRINS I AND II. *(E.)* Hansky, J.; Soveny, C.; Korman, M. G. (Prince Henry's Hosp., Melbourne, Australia). *Digestion* 10:97-107, 1974.

Two gastrin antisera with different specificity for gastrins I and II were compared by raioimmunoassay. One antiserum (AS 4) was produced in a rabbit by 3 i.m. injections of an emulsion of synthetic human gastrin I-bovine serum albumin conjugate with

Freund's adjuvant, to which fine charcoal was added followed by intrasplenic and i.p. injections and then further monthly i.m. injection for 5 months. The other antiserum (AS 35) was produced in a rabbit by repeated foot pad injection of the emulsion, followed by an i.m. boost 3 months after the last foot pad injection. AS 4 bound well with synthetic human gastrin I and porcine gastrin I, yet showed little cross-reactivity with porcine gastrin II, while AS 35 showed equal binding with porcine gastrins I and II and synthetic human gastrin I. Fasting serum gastrin levels in 49 normal control subjects, 53 patients with duodenal ulcer, 15 with gastric ulcer, 6 with pernicious anemia and 12 with Zollinger-Ellison syndrome were higher when measured with AS 35 than with AS 4. Levels in duodenal ulcer which were significantly lower than normal with AS 4, were normal or slightly higher than normal with AS 35. Responses of the various test groups to protein feeding, insulin hypoglycemia, and secretin injection were generally in the same direction with both antisera. This was not the case in some patients after complete truncal vagotomy whose serum gastrin in response to insulin hypoglycemia was unchanged with AS 4, but showed a small rise with AS 35. These results suggest that the form in which gastrin is secreted in duodenal ulcer disease may be as sulfated gastrin II rather than as non-sulfated gastrin I. Antibodies raised against gastrin II may shed more light on this hypothseis.

6463 USE OF LAPAROSCOPY IN THE DIAGNOSIS OF TUBERCULAR PERITONITIS. *(Sp.)* Hita Perez, J.; de Dios Vega, J.; Mino Fugarolas, G.; Diago Ferrero, A.; Mardomingo Varela, P.; Muro, J. (La Paz Munic. Sanitorium, Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 41(8):875-886, 1973.

A diagnosis of chronic peritonitis, probably tubercular in origin, was established in 16 of 1728 laparoscopies. In addition, 2 patients had peritoneal carcinomatosis, but a tubercular etiology could not be completely ruled out in either case. These 18 patients consisted of 10 men and 8 women, aged 18-70 yr (mean age 37 yr). Laparoscopic signs suggestive of tuberculosis were (1) dull, hyperemic, congested peritoneum enlarged by fibrinous exudation, in some cases with white areas resembling the white of a hard-boiled egg; (2) foamy, greenish ascites fluid; (3) interserosal adhesions which occasionally anchored the intestinal loops, which were sometimes dilated, to the parietal peritoneum; and (4) circumscribed or diffuse nodules on the parietal and visceral peritoneum, surfaces of the liver and spleen, and adherent tracts. Of the 9 patients from whom peritoneal biopsies were taken, *Mycobacterium tuberculosis* was isolated from tuberculoid granulomas in 8. The 1 patient who was negative for *M. tuberculosis* was shown to have a sigmoid carcinoma by barium enema. Three of the 4 nonbiopsied patients, whose laparoscopic and clinical findings were considered indicative of tubercular peritonitis, responded to tuberculostatic agents; the remaining patient had to be transferred to another hospital for treatment of pulmonary tuberculosis. Of 3 patients who were only subjected to liver biopsy, 2 had signs of granulomatous hepatitis, with a caseous granuloma in 1; the remaining patient had no detectable lesions. The patient with the caseous granuloma had clinical symptoms of typhoid fever and improved on specific therapy. One of the other patients died of an adenocarcinoma of the colon which, at autopsy, was found to have metastasized to the liver, gallbladder, spleen, peritoneum and bladder, while the other patient had a mucous cystadenoma of the ovary. These findings illustrate how difficult it may be to establish or rule out a diagnosis of tubercular peritonitis.

6464 HYPERSECRETORY STATES OF THE PANCREAS: IMPLICATIONS FOR THE PHYSIOPATHOLOGY OF PANCREATIC INFECTION. *(Sp.)* Dreiling, D. A.; Greenstein, A.; Bordalo, O. (Mt. Sinai Sch. Med., New York, N.Y.). *G.E.N.* 27(3/4):205-211, 1973.

For 80 min after stimulation with secretin (1.0 U/kg i.v.), pancreatic secretion was studied in 44 patients with biliary cirrhosis, 39 with nonalcoholic cirrhosis, 94 with alcoholic cirrhosis, 11 with Zollinger-Ellison syndrome, 19 with hemochromatosis, and 257 normal controls. In patients with biliary and nonalcoholic cirrhosis, the mean values for the pancreatic and bicarbonate outputs were higher than those found in normal subjects, but these values did not fall outside the normal range. In patients with Zollinger-Ellison syndrome and hemochromatosis, values for mean pancreatic and bicarbonate outputs were higher than in normal subjects and were increased above the normal range. Values for pancreatic and bicarbonate outputs fell between these 2 groups in patients with alcoholic cirrhosis. These findings suggest that patients with biliary and nonalcoholic cirrhosis do not have pancreatic hypersecretion. Increases in the mean pancreatic and bicarbonate outputs may be due to an increase in the ductular mass in the liver. Pancreatic hypersection appears to be functional in Zollinger-Ellison syndrome and to result from an increase in the pancreatic ductular mass in hemochromatosis. Increased pancreatic secretion in alcoholic cirrhosis is interpreted as being due to increases in the ductular cell mass in both the pancreas and liver.

6465 THE NATURE AND SIGNIFICANCE OF HYPERAMYLASEMIA FOLLOWING OPERATION. *(E.)* Morrissey, R.; Berk, J. E.; Fridhandler, L.; Pelot, D. (Dept. Med., Univ. California, Irvine). *Ann. Surg.* 180(1): 67-71, 1974.

Since the diagnosis of acute postoperative pancreatitis is usually based on the presence of hyperamylasemia, the isoenzyme pattern of serum amylase elevation following various abdominal and nonabdominal operative procedures was studied in a randomly selected group of 110 patients. Total serum anylase activity was significantly elevated postoperatively in 11 (10%) of the patients: of 28 patients undergoing abdominal operations, 4 (14%) had amylase increases; of 82 patients with nonabdominal surgery, 7 (9%) showed serum amylase elevations. In 7 of the 11 patients showing postoperative serum amylase elevations, isoamylase analysis revealed that the rise was chiefly in the pancreatic-type isoamylase; in the other 4 patients, the elevation occurred principally in the salivary-type isoamylase. These findings indicate that postoperative hyperamylasemia appears surprisingly often, and serum amylase activity may rise even when the surgical procedure is extra-abdominal. Moreover, elevation of serum amylase activity after surgery is not necessarily an indication of pancreatitis and may reflect instead a rise in salivary-type isoamylase.

6466 POSSIBLE INFLUENCE OF VITAMIN B_{12}-BINDING ON THE INTESTINAL FLORA IN BREAST-FED INFANTS: II. CONTENTS OF UNSATURATED B_{12}-BINDING PROTEIN IN MECONIUM AND FAECES FROM BREAST-FED AND BOTTLE-FED INFANTS. *(E.)* Gullberg, R. (King Gustaf V Res. Inst., Stockholm, Sweden). *Scand. J. Gastroenterol.* 9(3):287-292, 1974.

The amounts and patterns of unsaturated B_{12}-binding proteins in feces from breast-fed and bottle-fed infants were compared. A total of 76 samples were collected from 22 infants aged 1-51 days. The unsaturated vitamin B_{12}-binding capacity values (ng B_{12} U/g of meconium or feces) obtained were a mean of 154 (range 2-1151) and a median of 49 in 21 samples from 15 infants aged 1-3 days; a mean of 273 (range 2-1300) and a median of 64 in 28 samples from 10 breast-fed infants aged 4-51 days; and a mean of 72 (range 0-468) and a median of 10 in 27 samples from 9 bottle-fed infants, aged 4-51 days. The known properties of the large molecular size B_{12}-binding protein and the estimated amounts of the protein in human digestive fluids and milk agree with the idea that the protein could exert a selective antimicrobial effect by competing with certain microorganisms for vitamin B_{12} or analogues of B_{12} in the gastrointestinal contents. The protein might thus interfere with a synergistic effect of microorganisms synthesizing vitamin B_{12} or analogues thereof on microorganisms requiring exogenous supply of such compounds. The B_{12}-binding protein in granulocytes and external secretions may be important in host-parasite interactions. It may also participate in defense mechanisms against opportunistic bacteria dependent on an exogenous supply of B_{12}.

6467 INTESTINAL ABSORPTION OF 25-HYDROXYCHOLECALCIFEROL. *(E.)* Stamp, T. C. B. (Roy. Natl. Orthopedic Hosp., London, England). *Lancet* (7873):121-123, 1974.

A single dose of 10 μg/kg of 25-hydroxycholecalciferol in propylene glycol or vegetable oil was administered p.o. to 12 healthy volunteers (7 males and 5 females, aged 19-42 yr) and 10 patients (2 males and 8 females, aged 23-75 yr) with disorders in calcium metabolism and/or gastrointestinal function. Diagnosis included partial gastrectomy (3) and 1 case each of visceral scleroderma, primary biliary cirrhosis, autoimmune hepatitis, carcinoma of the head of the pancreas, complete obstructive jaundice, classic vitamin D deficiency with osteomalacia, and primary hyperparathyroidism. Plasma levels of 25-hydroxyvitamin D were measured by radiostereoassay at intervals during the next 24 hr. The mean maximum rise in plasma 25-hydroxyvitamin D was 109 ng/ml in healthy subjects. This rise occurred either 4 or 8 hr after 25-hydroxycholecalciferol ingestion. Of the 10 patients, 5 had markedly abnormal results, clearly demonstrating the abnormalities of vitamin D absorption which can occur after partial gastrectomy, in small bowel disease, and in biliary dysfunction. A 25-hydroxycholecalciferol tolerance test may thus be of value in establishing the cause of osteomalacia in gastrointestinal disease. Response to treatment of the primary disease may also be monitored by this technique. The test provides either rapid initial therapy or a clear indication for parenteral vitamin D administration in biliary disease.

GENERAL

Parasitology

6502 HYPERINFECTION WITH Strongyloides stercoralis IN GREAT BRITAIN. *(E.)* Royle, G.; Fraser-Moodie, A.; Jones, M. W. (Hammersmith Hosp., London, England). *Br. J. Surg.* 61(6):498-500, 1974.

A 29-yr-old Jamaican woman presented with acute abdominal pain associated with vomiting, abdominal distension, and constipation. She had lived in England for 13 yr and had been shown to be a carrier of *Strongyleides stercoralis* 8 yr prior to her present illness, but no treatment had been instituted at that time. After a diagnosis of *S. stercoralis* was made, treatment with thiabendazole (25 mg/kg, twice daily) was instituted via a Ryle's tube. During therapy the SGOT rose from 12 to 76 U/liter and alkaline phosphatase rose from 26 to 350 U/liter. These later returned to normal. On day 15, a repeat biopsy showed regenerating mucosa with no larvae present. In this patient there was no apparent underlying condition. Her entire illness could be explained by reaction within the intestinal mucosa causing malabsorption and fluid and electrolyte imbalance. No evidence was noted of circulation of parasites and, in particular, no peripheral eosinophilia. A review of past cases indicates that all carriers of the nematode should be treated immediately, that no immigrant from an endemic area should be treated with corticosteroid or other immunosuppressives until the stools have been examined, and that diagnosis of *Strongyloides* hyperinfection should be considered in any immigrant with acute abdominal pain before laparotomy is undertaken. It is recommended that patients receive long courses of thiabendazole as a relapse may occur many months or even years later.

6503 HEPATIC ASCARIASIS. A CASE REPORT AND REVIEW OF THE LITERATURE. *(E.)* Saw, H. S.; Somasundaram, K.; Kamath, R. (Univ. Hosp., Kuala Lumpur, Malaysia). *Arch. Surg.* 108(5):733-735, 1974.

Although biliary ascariasis is common, the hepatic variety is rare. In this case report of hepatic ascariasis, a 2-yr-old Chinese boy in Malaysia passed large roundworms in stools on 4 occasions prior to admission for anorexia and fever associated with sweating. Laboratory findings included a total white cell count of 22,500/mm^2 (neutrophils, 77%, lymphocytes, 21%, and monocytes, 2%). Stool examination disclosed *Ascaris* ova, while an abdominal roentgenogram showed an enlarged liver but no other abnormality. At laparotomy, the liver was congested, with numerous linear areas of induration; these were incised and found to contain adult *Ascaris lumbricoides* worms. Liver biopsy revealed severe inflammation and fibrosis with many *Ascaris* ova in the tissue. All accessible, indurated areas were incised and the ascarids evacuated. After surgery, the child was given a 4-day course of piperazine citrate therapy (750 mg/day p.o.) to eradicate residual worms in the liver. Large numbers of adult *Ascaris* worms were passed by the rectum starting on postoperative day 6, but the child continued to have a high, oscillating temperature. Diethylcarbamazine citrate (20 mg 3 times/day p.o.) was then given for 3 weeks, at which time the temperature subsided and the patient's general condition improved. One yr after discharge the child has had no recurrence of symptoms. Whether diethylcarbamazine therapy contributed to his clinical improvement is uncertain.

6504 STUDY OF MAGNESIUM METABOLISM IN PARASITIC DISEASES OF THE COLON IN FLIGHT PERSONNEL. *(Fr.)* Pesquies, P.; Pannier, R.; Bon, R.; Girod, F. X.; Hadni, J. C. (Res. Ctr. Aviation Med., Paris, France). *Rev. Med. Aeronaut. Spatiale* 12(46):234-236, 1973.

An analysis was made of electromyogram tracings, plasma and erythrocyte magnesium, and whole blood calcium values in 22 male flight personnel with chronic parasitic diseases of the colon and symptoms of latent spasmophilia (lipothymia, feeling of a lump in the esophagus, thoracic oppression, etc.) and in 145 controls. All subjects examined were aged 25-50 yr. A significant increase in the frequency and intensity of repetitive electromyographic anomalies was found among the patients (68% compared with 9% among controls). Although no significant differences in plasma magnesium or whole blood calcium were found between patients and controls, erythrocyte magnesium concentrations were significantly decreased in patients (4.45 mEq/liter compared to 4.82 mEq/liter among controls). Thus, neurovegetative disorders observed in these patients may be due to a magnesium deficiency. Since latent spasmophilia in these patients might become manifest with spontaneous hyperventilation which is common among flight personnel, it is recommended that treatment of parasitic diseases of the colon be combined with a magnesium supplement (5 mg/kg/day Mg^{++}p.o.), a magnesium-binding agent such as pyridoxine, and a sedative for neuromuscular hyperexcitability.

6505 A CASE OF AMOEBIASIS OF THE RECTUM. *(E.)* Rossi, L. F. A. (Queen Mary's Hosp., London, England). *Br. J. Clin. Pract.* 28(6):212-214, 1974.

Regional Enteritis

6506 STUDIES ON CROHN'S DISEASE. III. CONCENTRATIONS OF IMMUNOGLOBULINS G, A, AND M IN THE MUCOSA OF THE TERMINAL ILEUM. *(E.)* Persson, S. (Regional Hosp., Orebro, Sweden). *Acta Chir. Scand.* 140(1):64-67, 1974.

Concentrations of immunoglobulins G, A. and M were measured by radial immunodiffusion in serum and homogenized·mucosa from the terminal ileum of 10 patients with Crohn's disease (4 men and 6 women, aged 19-46 yr) and 6 control patients (4 men and 2 women, aged 25-77 yr). Compared with controls, immunoglobulins were markedly increased in tissue homogenates from subjects with Crohn's disease, but serum immunoglobulin concentrations were within normal ranges. IgG concentrations were higher than IgA and IgM concentrations in patients with Crohn's disease and in controls. In Crohn's disease, the mean tissue concentration of IgG was 1.99 mg/g tissue *versus* 0.8 mg/g for IgA and 0.88 mg/g for IgM. These results are in agreement with an earlier study showing an overall increase in immunoglobulin-containing cells, particularly IgG-containing cells, in the terminal ileum of patients with Crohn's disease. The data indicate that there is a local immune response in the inflamed intestinal tissue of patients with Crohn's disease.

507 A STUDY OF PERIPHERAL LEUCOCYTE MIGRATION IN AGAROSE MEDIUM IN INFLAMMATORY BOWEL DISEASE. *(E.)* Bartnik, W.; Swarbrick, E. T.; illiams, C. (St. Mark's Hosp., London, England). *ut* 15(4):294-300, 1974.

ntigens of *Escherichia coli* 014 share determinants ith colonic antigens extractable from germ-free astrointestinal mucins, suggesting bacterial antiens play a role in cell-mediated immune mechanisms which may be involved in the pathogenesis of ulcerative colitis and Crohn's disease. The present work was carried out to determine whether the common antigen of Kunin, known to be present in *E. coli* 014 and to be related to antigens deriving from germ-free rat colon or feces, might show reactivity with sensitized leukocytes by inhibiting their migration in agarose medium. Such sensitized leukocytes might be expected in patients with ulcerative colitis. An attempt was also made to find a simple immunological test to distinguish ulcerative colitis from Crohn's disease. Antigens other than that of Kunin which were tested included an extract from germ-free rat feces and a Kveim suspension from sarcoid spleen K19. Inhibition of migration was obtained only with the Kunin antigen. It was observed in 11 out of 20 patients with ulcerative colitis and in 4 of 20 patients with Crohn's disease, but in only 1 of 33 controls. The occurrence and degree of migration inhibition appeared to be related to the activity of ulcerative colitis. Although leukocyte migration inhibition with Kunin antigen was almost 3 times as frequent in patients with ulcerative colitis as in those with Crohn's disease, the degree of inhibition was the same in both groups. It is clear that the test is not useful for distinguishing the 2 conditions. The observed lack of cellular reactivity to extract from germ-free feces and Kveim suspension contrasts with results obtained by other investigators using the capillary tube method. Results with the Kunin antigen support the hypothesis that a state of cellular immunity to enterobacterial common antigen may exist in inflammatory bowel disease.

6508 FAT-REDUCED DIET IN THE SYMPTOMATIC TREATMENT OF SMALL BOWEL DISEASE. METABOLIC STUDIES IN PATIENTS WITH CROHN'S DISEASE AND IN OTHER

PATIENTS SUBJECTED TO ILEAL RESECTION. *(E.)* Andersson, H.; Isaksson, B.; Sjogren, B. (Sahlgren Hosp. Goteborg, Sweden). *Gut* 15(5):351-359, 1974.

Eleven patients (6 men and 5 women, aged 19-61 yr) with Crohn's disease, of whom 9 had ileal resection, and 2 patients (a 52-yr-old man and a 63-yr-old woman) with small bowel resection for trauma and ileus were studied under metabolic ward conditions for an average period of 32 days. Most of these patients had chronic, severe diarrhea and varying degrees of steatorrhea; all were given 2 levels of fat intake: high-fat (100 g/day) for 2-4 days, followed by low-fat (40 g/day) for 16-24 days. On the high-fat diet, all patients showed watery diarrhea; but after the introduction of the low-fat diet, a marked reduction in number of stools and in fecal excretion of water and sodium occured in most patients, with 10 passing solid feces. Two other subjects improved only after the addition of cholestyramine (4 g 2-3 times/day). In 1 patient with colectomy and ileostomy, no improvement was seen. On the low-fat diet, there was a positive balance of nitrogen and potassium in many cases. Fecal fat excretion decreased to an average of 10 g/day from a mean of 23 g/day on the high-fat diet, but there was no change in the fractional absorption of fat. Clinical improvement was most marked in 6 patients with functioning gallbladders. In general, previous resection of the colon seemed to limit the reduction of fecal water and sodium excretion which followed the reduction in fat intake. These studies indicate that a fat-reduced diet can be recommended for symptomatic therapy of chronic diarrhea in patients with diseases of the ileum.

6509 ACUTE TOXIC DILATION OF THE COLON IN CROHN'S COLITIS. *(E.)* Buzzard, A. J.; Baker, W. N. W.; Needham, P. R. G.; Warren, R. E. (Gordon Hosp., London, England). *Gut* 15(5):416-419, 1974.

A study of case records of 190 patients with Crohn's disease seen over a 14-yr period revealed that 12 (6%) developed acute toxic dilation of the colon which was treated by total colectomy and ileorectal anastomosis. The mean age of these 12 patients (9 women and 3 men) was 29 yr at time of operation. All patients had been treated with systemic steroids, and in all 10 cases the duration of symptoms prior to the acute episodes was less than 2 yr. Clinical findings indicative of acute toxic dilation of the colon were preoperative oral temperatures above 100 F in 11 cases, a WBC over 10,000 in 8, a pulse rate over 120 in 10, and erythrocyte sedimentation rate over 30 mm/hr in 10. Dilation of the colon observed at operation was closely correlated with the maximum width (>10 cm) of the transverse colon measured in formalin-fixed sections. Fibrosis was present in the submucosa and subserosa but was definitely less evident in the transverse colon than in other parts, suggesting that steroids delayed the development of fibrous tissue in the most severely inflammed area. Only 4 patients still have successfully functioning ileorectal anastosomes at 8 months, to 8 yr. Four required a permanent ileostomy and 4 died. The preoperative sigmodoscopic appearance of the rectum was of no value in predicting the recurrence of disease.

6510 AN EXPERIMENTAL ANIMAL MODEL OF CROHN'S DISEASE. *(E.)* Cave, D. R.; Mitchell, D. N. (St. George's Hosp., London, England). *Gut* 15(4):345, 1974.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

CONTENTS

PRE-CLINICAL SCIENCES

	Abstracts, Citations	Page

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

6517 QUANTITATIVE ULTRASTRUCTURAL STUDIES ON INHIBITED AND ON PARTLY STIMULATED GASTRIC PARIETAL CELLS.

(E.) Helander, H. F.; Hirschowitz, . I. (Dept. Anat., Univ. Umea, Sweden). *Gastroenterology* 67(3):447-452, 1974.

Six gastric fistula dogs, fasted overnight, were studied after inhibition of gastric acid secretion by atropine sulfate (80 μg/kg s.c.) and at the onset of secretion stimulated by constant i.v. infusion of histamine (50 μg/kg/hr). Gastric biopsies were taken 2 hr after inhibition of acid secretion and, with histamine infusion, during the transition from the resting to the secreting state. Morphometric data obtained from selected parietal cells in these dogs was compared with that obtained previously for dogs before, during, and after maximal histamine stimulation. The volume density of the mitochondria in atropine-inhibited and in presecretory dogs was about the same as in the resting and maximally stimulated dogs of the earlier study. However, the mitochondrial volume density was significantly lower in the partly stimulated dogs than in dogs biopsied 1 hr after maximal histamine stimulation. In the atropinized dogs, the surface densities of the secretory and tubulovesicular membranes were similar to the values previously obtained in resting dogs. In the partly stimulated dogs, the corresponding surface values were about the same as those for the posthistamine dogs. Surface densities of the nutrient membrane remained constant regardless of the functional state of the cells. In both studies, there was a delay in response after stimulation before gastric secretion started. At the end of this period, when secretion was minimal, significant morphological changes had already occurred. Therefore, the structural changes stimulated by histamine occur in the latent period before secretion starts.

6518 ACID MUCOSACCHARIDE-CONTAINING STRUCTURES IN THE GALL BLADDER EPITHELIUM OF THE RABBIT AS SEEN WITH THE ELECTRON MICROSCOPE.

(E.) Yamada, K. (Nagoya Univ. Sch. Med., Japan). *Histochemistry* 39(4):351-360, 1974.

Acid mucosaccharide containing ultrastructures in specimens of gallbladder epithelium treated with dialyzed iron, colloidal thorium, and ruthenium red were studied with the electron microscope. In epithelium stained with dialyzed iron, both extra- and intracellular ultrastructures were reactive. These included the surface coat of the plasma membrane, pinocytotic vesicles, granules of secretion, and certain elements of the Golgi apparatus. In the epithelial tissues stained by colloidal thorium or ruthenium red, the surface coat of the plasma membrane was the only ultrastructure which reacted positively for acid mucosaccharide. The present picture of ultrastructural elements containing acid mucosaccharides indicates a multiple function of the substances in rabbit gallbladder epithelium and correlates well with results of previous light and electron microscopic studies on the gallbladder epithelium of various vertebrate species.

6519 CIRCULAR MUSCLE LAYERS IN THE SMALL INTESTINE.

(E.) Duchon, G.; Henderson, R.; Daniel, E. E. (Dept. Pharmacol., Univ. Alberta, Edmonton, Canada). *Proc. Int. Symp. Gastrointest. Motility, 4th, 1973* pp. 635-646.

Circular muscle layers from the small intestine of female mongrel dogs were examined by electron microscopy. Two layers were delineated: a main body of circular muscle and a more dense layer (6-12 cells thick) adjacent to the submucosa and containing smooth muscle cells which were more closely packed than those of the main body of muscle. The dense layer was almost completely separated from the rest of the circular muscle by a layer of nerve axons and connective tissue cells. No nexus (gap junctions) were observed between cells of the inner dense layer, while such contacts were numerous in the main outer layer. Nerve axons were rarely observed between cells in the dense layer but were abundant in the main circular muscle layer. Muscle cells of the main outer layer made occasional nexal contacts with cells of the intervening plexus layer, while muscle cells of the dense layer did not. The plexus layer contained unusual cells which in some portions resembled smooth muscle cells with typical actin filaments and plasmalemmal vesicles; in other portions, the plexus cells resembled Schwann cells or interstitial cells in their appearance and close applications to nerve axons. These hybrid cells formed gap junctions with the outer circular muscle layer. No nerve cell bodies were identified in the plexus. Axon varicosities were largely of two types: most consisted of small agranular vesicles typical of cholinergic nerves and some were large dense-cored granules. Results obtained after vagotomy and local denervation suggest that both pre- and postganglionic fibers, and perhaps afferent nerves, are present in this plexus.

6520 IMMUNOHISTOCHEMICAL AND ULTRASTRUCTURAL STUDIES ON THE ENDOCRINE POLYPEPTIDE (APUD) CELLS OF THE AVIAN GASTROINTESTINAL TRACT.

(E.) Polak, J. M.; Pearse, A. G. E.; Adams, C.; Garaud, J. C. (Hammersmith Hosp., London, England). *Experientia* 30(5):564-567, 1974.

The identification of endocrine cells, and the localization of the hormones gastrin, glucagon, secretin, vasoactive intestinal peptide (VIP), and gastric inhibitory peptide (GIP) were studied in the gut of the quail and White Leghorn chicken. The methods utilized were immunofluorescence and peroxidase-labeling. Gastrin and cerulein were found in cells of all regions except the proventriculus and cecum with only gastrin cells in the gizzard; secretin, in cells of the duodenum and 1st part of the jejunum; glucagon, in cells of the 2nd part of the duodenum, the jejunum, and the ileum; and VIP in cells of all regions except the gizzard. No GIP cells were found in any part of the G.I. tract. All endocrine cells were reactive with lead hematoxylin and Grimlius silver but not reactive with the Masson-Fontana method for enterochromaffin granules. This demonstrates that none of the hormones mentioned is present in the enterochromaffin cells, but all are present in argyrophil cells. Preliminary studies show that glucagon and secretin are stored in different cells. No distinction was found between glucagon and gastrin cells. Gastrin and cerulein reactin cells were identical. This data is in agreement with previous observations recorded on the distribution of gastrin, glucagon, secretin, and VIP in avian gut endocrine cells.

39 ABSORPTION AND TRANSPORT OF PROTEIN FROM
THE PERITONEAL CAVITY.

(E.) Szabo, G.;
gyar, Z. (Natl. Inst. Traumatol., Budapest, Hun-
ry). *Acta Med. Acad. Sci. Hung.* 30(4):303-310,
73.

sorption of ^{131}I-albumin from the diaphragmatic
pect of the peritoneum, from the liver, and from
e intestinal serosa was measured in 58 mongrel
gs. Absorption from the diaphragm was slow. Af-
r 6 hours, only 1.6% of the introduced radioalbu-
n was recovered in the thoracic duct lymph, 1.9%
om the lymph flowing from the cannulated right
ct, and 8.6% from the circulating plasma, giving
total of 12.1% for diaphragmatic absorption. Com-
rison with animals with ligated right lymph trunk
early indicated that the lymphatics terminating on
e right side of the neck are probably the most im-
rtant pathway for the transport of the protein ab-
rbed at the peritoneal aspect of the diaphragm.
sorption from the liver surface was more rapid
an the diaphragm. After 6 hr the total amount in
asma and lymph was 50.5%. In animals with ligated
ght duct, recovery in plasma and lymph was 28% of
e introduced dose, indicating the importance of
e lymphatics on the right side of the neck. Prac-
cally no absorption was noted from the serosa of
e jejunum. These results indicate that liver sur-
ce is the most important site of protein absorp-
on from the abdominal cavity. These experiments
so suggest that protein may be removed from the
ritoneal space by absorption into blood capillar-
s. At the peritoneal aspect of the diaphragm, the
tio of venous *versus* lymphatic transport was 0.66
ile the same ratio for absorption from the liver
psule was 0.59, indicating that nearly 40% of the
tal absorbed protein entered directly into the
ood capillaries. The lymphatics joining the great
ins at the right side of the neck carried about
ice as much absorbed protein as did the thoracic
ct.

40 COMPETITION BETWEEN CARNOSINE AND OTHER
PEPTIDES FOR TRANSPORT BY HAMSTER JEJUNUM
VITRO.

(E.) Addison, J. M.; Matthews, D. M.;
rston, D. (Westminster Med. Sch., London, England).
in. Sci. Mol. Med. 46(6):707-714, 1974.

take of carnosine in the rings of everted hamster
junum incubated *in vitro* at 27 C was inhibited by
uimolar glycylglycine, glycylglycylglycine, glycyl-
rcosine, glycylproline, methionylmethionone and pro-
lhydroxyproline but not by the equivalent free ami-
acids, or by a mixture of β-alanine and histidine.
hibition of carnosine uptake by glycylproline was
mpetitive. Possibly carnosine and the dipeptides
hibiting its uptake enter the mucosal cells by a
mmon mechanism which is independent of the entry
chanisms for amino acids. Uptake of carnosine was
t inhibited by *N*-acetylglycylglycine or by glycyl-
ycine amide, suggesting that these substitutions
event glycylglycine from utilizing the dipeptide-
take mechanism. Carnosine uptake was not inhibited
equimolar lysyllysine or α-glutamylglutamic acid,
r did either lysyllysine or α-glutamylglutamic acid
fect uptake of each other. Though these results
e compatible with the existence of multiple dipeptide-uptake systems in the intestinal mucosa, the evidence presently available is insufficient to permit any conclusion on this point.

6541 FUNCTIONAL DIFFERENTIATION OF HUMAN JEJUNUM AND ILEUM: A COMPARISON OF THE HANDLING OF GLUCOSE, PEPTIDES, AND AMINO ACIDS.

(E.) Silk, D. B. A.; Webb, J. P. W.; Lane, A. E.; Clark, M. L.; Dawson, A. M. (St. Bartholomew's Hosp., London, England). *Gut* 15(6):444-449, 1974.

Absorption rates of the dipeptide glycyl-L-alanine and its constituent free amino acids from the human ileum were compared by *in vivo* perfusion techniques in 6 adult volunteers (aged 19-58 yr). The positioning of the perfusion tube was verified by measuring the differential jejunal and ileal handling of bicarbonate. Differences in jejunal and ileal amino acid absorption were compared with differences in glucose absorption from the same perfusion sites. Glucose was absorbed faster from the jejunum (25.5 ± 2.87 mM/hr/15 cm) than from the ileum (14.0 ± 2.0 mM/hr/15 cm), resulting in a 45.5% reduction in mean glucose absorption rate between the proximal jejunum and ileum. L-alanine was absorbed faster than glycine both in the jejunum and the ileum from the amino acid solution. Glycine was absorbed faster from the jejunum (48.1 ± 10.6 μM/min/15 cm) than from the ileum (21.4 ± 6.9 μM/min/15 cm), with a 55.5% reduction in mean glycine absorption rate between the proximal jejunum and the ileum. For 5 subjects the mean absorption rate of L-alanine from the ileum was 68.3 ± 14.8 μM/min/15 cm, a 37.3% reduction from the rate of absorption from the jejunum, 83.2 ± 12.3 μM/min/15 cm. No significant difference was obtained in the net absorption rates of glycine or L-alanine from the dipeptide solution when perfused in the ileum compared with the jejunum. The absorption of glycine was faster from the dipeptide solution than from the equivalent amino acid solution during both jejunal and ileal perfusions. L-alanine was absorbed at similar rates from the jejunum during perfusion of the dipeptide solution and the amino acid solution. However, during ileal perfusions, L-alanine was absorbed faster from the dipeptide solution. These studies support the existence of separate mechanisms for amino acid dipeptide transport in man. The observation that a peptide is absorbed at the same rate in the ileum as well as the jejunum, whereas amino acid uptake is depressed compared with the jejunum, could indicate that oligopeptide transport plays a major role in distal absorption of protein digestion products.

6542 THE EFFECT OF FASTING ON HEXOSE TRANSFER IN RAT INTESTINE.

(E.) Sanford, P. A.; Smyth, D. H. (Dept. Physiol., Univ. Sheffield, England). *J. Physiol. (Lond.)* 239(21):285-299, 1974.

Accurately defined segments of rat intestine were isolated *in vivo* and *in vitro* to study the effects of fasting on glucose and galactose transport in the proximal jejunum and distal ileum. In the *in vivo* experiments, the transport of glucose and galactose in the distal ileum was stimulated by fasting. The effect was specific as neither amino acid transport nor the permeability of the luminal membrane of the absorbing epithelium was altered by fasting. The increased hexose transport was accompanied by a reduced accumulation of hexose in the intestinal wall. Fasting did not stimulate hexose transport in the proximal jejunum. In the *in vitro* experiments, galactose transport in both the distal ileum and proximal jejunum was greater in fasted than in fed animals. Galactose transfer was stimulated by mannose to a greater extent in fasted than in fed animals, and the stimulation was greater in the proximal jejunum than in the lower ileum. In the presence of mannose, fluoride inhibited fluid and galactose transfer to a greater extent in fed than in fasted animals, in both the distal ileum and the proximal jejunum. In fed animals, fluoride had less effect on fluid and galactose transfer in the distal ileum than in the proximal jejunum. The importance of hexose metabolism to hexose transport was confirmed by *in vivo* experiments which showed that transport in the presence of fluoride was faster in fasted than in fed animals. Motility studies showed that phenol red introduced into the stomach reached the ileum sooner, achieved a higher concentration, and remained there longer in fasted than in fed animals. The increased absorptive capacity of the lower ileum during fasting could be a useful physiological adaptation. The depression of carbohydrate metabolism in the jejunum could also be a useful adaptation, as more hexose would be available for those organs more dependent on carbohydrate.

6543 THE TRANSAMINATION OF GLUTAMATE AND ASPARTATE DURING ABSORPTION IN VITRO BY SMALL INTESTINE OF CHICKEN, GUINEA-PIG AND RAT.

(E.) Parsons, D. S.; Volman-Mitchell, H. (Dept. Biochem., Univ. Oxford, England). *J. Physiol. (Lond.)* 239(3): 677-694, 1974.

The rates and extent of transamination of glutamate and aspartate were measured over periods of up to 90 min during absorption *in vitro* by the small intestine of rat, guinea-pig, and chicken. In the technique used, Krebs-Ringer-glucose-bicarbonate saline containing glutamate, aspartate, or both was circulated through the lumen of intestinal segments *in vitro*. The 'sweat' secreted at the serosal side of the segment was collected at regular intervals and the content of glutamate, aspartate, and other amino acids, especially alanine, determined. During absorption of dicarboxylic amino acids by rat small intestinal segments, alanine contributed 85% of the amino acids in the fluid secreted at the serosal surface. Similar measurements in guinea-pig and chicken intestine showed the alanine portion not to exceed 60%. For each species, a relation was found between the extent of dicarboxylic amino acid transamination to alanine and the total glutamic-pyruvic transaminase found in the intestinal mucosa. The proportion of alanine in the total amino acids appearing at the serosal surface was similar in the jejunum and ileum of both rats and guinea-pigs. The rate of appearance of alanine in serosal fluid was greater in the ileum than in the jejunum of the rat. It is suggested that in each species there is a limit to the amount of free dicarboxylic amino acids which the small intestinal mucosa can subject to transamination. However, it seems unlikely that during the digestion and absorption of a protein meal *in vivo*, the concentrations of free dicarboxylic amino acids in the intestinal lumen will ever exceed the concentrations needed to overload the transamination mechanism.

6544 EMBRYONIC CHICK INTESTINE IN ORGAN CULTURE: INTERACTION OF ADENYLATE CYCLASE SYSTEM AND VITAMIN D$_3$-MEDIATED CALCIUM ABSORPTIVE MECHANISM.

(E.) Corradino, R. A. (New York State Vet. Coll., Cornell Univ., Ithaca). *Endocrinology* 94(6):1607-1614, 1974.

Duodenum from 20-day-old chick embryos was maintaine in organ culture with excellent preservation of mucosal structure. Addition of vitamin D$_3$ (26 μM) to the medium increased duodenal cyclic AMP within 3 hr This increase preceded the induction of calcium-binding protein synthesis and stimulation of ^{45}Ca uptake by vitamin D$_3$. Following a decline to control level at 6 hr, cyclic AMP levels increased in parallel wit calcium-binding protein concentrations and ^{45}Ca uptake for the remainder of the 48-hr culture period. A metabolite of Vitamin D$_3$ (1,25-(OH)$_2$-D$_3$) stimulate cyclic AMP after a 48-hr incubation but at a much lower concentration. Dibutyryl cyclic AMP or theophylline (1 mM each) enhanced ^{45}Ca uptake regardless of the presence of vitamin D$_3$ in the medium, and the effect of these agents was additive. Enhancement was greater in the presence of vitamin D$_3$. Calcium-binding protein synthesis was reduced 50% by dibutyr cyclic AMP or theophylline alone, and 75% by both agents in combination. Stimulation of calcium uptake by dibutyryl cyclic AMP began within 3 hr and persisted for 48 hr, while inhibition of calcium-binding protein began only after 24 hr. The effect of this agent was not due to the butyrate since Na butyrate (1 mM) had no effect on calcium-binding protein synthesis or calcium uptake. Dibutyryl cyclic AMP alon resulted in increased total protein and DNA concentrations in cultured tissue and also stimulated mucosal to serosal transport of calcium. In the presence of vitamin D$_3$, the actions of both agents were essentially additive. Effects of the sterol on calcium uptake and translocation, and on calcium-binding protein synthesis, were completely abolished by actinomycin D (2 μg/ml). These results indicate an interaction involving vitamin D$_3$, calcium-binding protein, adenylate cyclase, and the intestinal calcium absorptive mechanism.

6545 PATTERNS OF VITAMIN B$_{12}$ ABSORPTION IN HUMANS MEDIATED BY HOMOLOGOUS AND HETEROLOGOUS INTRINSIC FACTORS.

(E.) Ranlov, P.; Rask-Madsen, J. (Glostrup Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(3):327-334, 1974.

The relative potencies of human gastric juice, dried hog pyloric mucosa, purified hog intrinsic factor, and rat gastric juice in the absorption of vitamin B$_{12}$ were studied in 27 normal subjects and in 6 patients with pernicious anemia. A paired radiolabel technique was employed by which homologous together with a heterologous intrinsic factor-vitamin B$_{12}$ complex was administered both p.o. and *via* tube directly into the intestine at various levels. Human and

intrinsic factors were equally effective in pro-
ing vitamin B_{12} absorption, regardless of the route
administration. In all subjects investigated sig-
icantly less vitamin B_{12} was absorbed when admini-
ered in complex with crude hog intrinsic factor, and
absorptive tendency decreased the more aboral the
paration was instilled. The poor performance of
crude hog preparation is attributed to its need to
s the upper intestinal tract to be available for
ecific B_{12} receptor sites in the ileum. This may be
plained as the need for proteolytic action on the
specific B_{12} binders. The use of crude hog stomach
eparations is questionable, particularly under con-
tions of impaired intestinal or pancreatic functions.
iable and easily standardized human intrinsic fac-
preparations are preferable.

46 THE EFFECT OF AMINO ACIDS ON THE INTESTINAL ABSORPTION OF IMMUNOGLOBULINS IN THE NEO-
TAL RAT. *(E.)* Bamford, D. R.; Donnelly, H. (Dept.
ol., Queen's Univ., Belfast, Ireland). *Immunology*
(1):151-158, 1974.

investigation was made to determine whether amino
ids which are actively transported and immunoglo-
lin G share common receptor sites during absorp-
on in 10-day-old Wistar rat ileum. The L-stereoiso-
rs of neutral amino acids (alanine, leucine, and
thionine) and histidine were absorbed against a
ncentration gradient from a 5 mM solution. Aspar-
c acid was not absorbed against a concentration
adient. Under anaerobic conditions with 100% ni-
ogen, the uptake of leucine and alanine was signi-
cantly reduced, and inhibition of leucine transport
curred in the presence of 0.2 mM 2,4-dinitrophenol.
ese results suggest that active processes for the
ansport of neutral and basic amino acids are al-
ady established in the ileum by 10 days postpartum.
e ileal absorption of ^{131}I-labeled rat IgG was sig-
ficantly greater than that of bovine IgG, confirm-
g the greater transport of the homologous protein
this *in vitro* system. The effect of relatively
gh concentrations of a number of neutral and charged
ino acids on the uptake of ^{131}I-labeled rat IgG
s examined. None of the neutral amino acids or as-
rtic acid significantly affected uptake. However,
th of the basic amino acids (lysine and arginine)
gnificantly stimulated the absorption of IgG.
imulation of protein uptake in the neonatal intes-
ine may be due to stimulation of pinocytosis by in-
eraction of positively charged molecules with the
lycocalyx on the apical cell membrane.

547 DRUG PERMEATION THROUGH MEMBRANES III: EFFECT OF pH AND VARIOUS SUBSTANCES ON PERM-
ATION OF PHENYLBUTAZONE THROUGH EVERTED RAT INTEST-
NE AND POLYDIMETHYLSILOXANE. *(E.)* Lovering, E. C.;
lack, D. B. (Drug Res. Branch, Hlth., Welfare Canada,
ttawa). *J. Pharm. Sci.* 63(5):671-676, 1974.

he permeation rate of phenylbutazone through membranes
f polydimethylsiloxane and everted intestine from male
prague-Dawley rats was measured over a range of pH
alues (5.00-7.40). The classical pH-partition hypothesis was not obeyed. Permeability coefficients were calculated using a modification of Higuchi's general equation relating pH and permeation rate. The effect of various substances on the permeability coefficient was determined. Phenylbutazone permeation rates in one or both membranes decreased in the presence of gelatin, methylcellulose, polyvinylpyrrolidone, skim milk, albumin, sodium lauryl sulfate, polysorbate 80, and cetrimonium bromide. Permeation rates through everted intestine were enhanced by bile salt concentrations below the critical micelle concentration and by porcine mucin, while rates through polydimethylsiloxane were unaffected. Substances having no apparent effect were: lactose, starch, talc, kaolin, calcium chloride, acacia, calcium sulfate, sucrose, sodium saccharin, cholesterol, ferrous sulfate, and magnesium stearate. None of the excipients examined significantly affected the permeation of phenylbutazone when present in concentrations liable to be used in formulating a drug. Interactions with a number of other materials found in the gastrointestinal tract occurred but these materials cannot be avoided *in vivo*.

6548 EFFECT OF HEMORRHAGE ON ELECTRICAL AND pH GRADIENTS IN THE INTACT STOMACH OF THE SUBHUMAN PRIMATE. *(E.)* Ritchie, Jr., W. P. (Univ. Virginia Med. Ctr., Charlottesville). *Gastroenterology* 67(2):259-263, 1974.

In 6 rhesus monkeys of both sexes (*Macaca mulatta*), cannulation of an acid test solution into their innervated intact stomachs was performed to monitor electrical potential differences (mV) generated by the gastric mucosa, and to assess net fluxes of water (ml), and of H^+, Na^+, and K^+ (μEq) at the end of a 3-hr period of hemorrhagic shock and again 3 hr after reinfusion of the shed blood. In addition, the effect of anesthesia alone on potential differences was measured over a 6-hr period in 4 control rats anesthetized with 0.1 mg/kg phencyclydine-HCl i.m., supplemented by 0.01 mg/kg given every 2.5 hr. In a further study, acid test solution containing 10 mM sodium taurocholate, a known agent for impairing the gastric mucosal barrier, was introduced into the stomachs of 4 controls. The resting state potential differences ranged from -43 to -49 mV; levels after hemorrhage, after reinfusion, and with anesthesia alone showed no significant alterations. Taurocholate caused a prompt fall in potential difference but values returned to base-line levels within 35 min after taurocholate evacuation from the stomach. In the basal state, a net gain of water, Na^+, and K^+, as well as a net loss of H^+ were observed. Neither hemorrhage nor subsequent reinfusion produced any significant changes, but taurocholate administration caused statistically significant increases in both the gains (water, Na^+, and K^+) and the H^+ loss of basal levels. The data indicate that in subhuman primates neither hemorrhage nor subsequent reinfusion of shed blood is associated with any significant changes in the ability of the intact stomach to maintain potential differences and pH gradients. These results do not substantiate the belief that acute posttraumatic hemorrhagic gastritis in humans is a consequence of an incompetent gastric mucosal barrier.

6549 AN EVERTED GUT POUCH TECHNIQUE WITH SIMULATED PERISTALSIS. *(E.)* Ghafoor, A.; Hartman, G. C.; Seddon, R. M.; Walker, R. (Dept. Biochem., Univ. Surrey, Guildford, England). *Biochem. Soc. Trans.* 2(3):545-547, 1974.

An 8-10 cm section of rat jejunum or upper ileum was everted with the proximal end tied to the glass cannula and the distal end ligated. The apparatus was arranged with two assemblies operating in parallel off the same gas cylinder and through a common outlet tube. The mucosal and serosal solutions of amino acids were initially of the same composition. Gas was bubbled through the mucosal solution, *via* the humidifier, then released into the atmosphere through peristalsis tubing. This tubing was periodically occluded by a motor-driven cam leading to a pressure pulse on the mucosal side. The serosal side was exposed to atmospheric pressure and thus these pulses led to a rhythmic contraction and expansion of the gut pouch. During contraction, serosal fluid was forced up the cannula and into contact with the aerating probe, serving both to mix serosal contents and facilitate serosal aeration. D- and L-Alanine were used to compare this technique with the gut sac technique of Wilson and Wiseman. The uptake of L-alanine was significantly greater than the D isomer in both procedures. Histological examination of tissues after 1-hr incubation showed far less overt damage in the gut pouch preparation than in the gut sac, and this was reflected in a significantly greater active transport for the L-amino acid. These factors, coupled with the ease of sampling, suggest this modified technique may be advantageous over other methods.

6550 CONTINUOUS RECORDING OF MULTIPLE PARAMETERS DURING PERFUSION OF HUMAN COLON. *(E.)* Chauve, A.; Devroede, G.; Sasseville, J. L. (Gastrointest. Res. Unit., Univ. Sherbrooke, Quebec, Canada). *J. Appl. Physiol.* 37(2):241-246, 1974.

A technique was developed to allow continuous recording of intraluminal pressure and potential difference during steady-state conditions of colonic perfusion in man. The method demonstrated the simplicity of pressure waves in the perfused right colon and permits simultaneous study of potential difference and movement of water and electrolytes. The technique was demonstrated on 8 male volunteers (aged 19-25 yr). During colonic perfusion with isotonic saline (15 ml/min), after establishing steady-state conditions, a potential difference of 17.4 mV was noted in the right colon, mucosa being negative. Impedence of the system varied little during the experiments but in the same individual potential difference fluctuated with time and was markedly influenced by the perfusion. Pressure waves were simple and periodic. Their amplitude ranged from 11.1-25.4 cm H_2O; their duration, 16-35 sec; and their frequency, 0.10-0.90 wave/min. They were accompanied by a subjective impression of contraction in the right iliac fossa. This method permits control of more variables during the study of potential difference and colonic pressure.

MOTILITY

6571 NATURE AND KINETICS OF INHIBITION OF LOWER ESOPHAGEAL SPHINCTER PRESSURE BY GLUCAGON. *(E.)* Jaffer, S. S.; Makhlouf, G. M.; Schorr, B. A.; Zfass, A. M. (Med. Coll. Virginia, Richmond). *Gastroenterology* 67(1):42-46, 1974.

The lower esophageal sphincter response to prompt i.v. injection of pentagastrin (0.25-1 µg/kg) alone or in combination with i.m. glucagon (10 µg/kg) was investigated in 4 healthy men. After pentagastrin injection, lower esophageal sphincter pressure rose rapidly to a peak in 1.5 min and returned to control levels in 4-5 min. The increase in pressure was dose-dependent, with 0.75 µg/kg pentagastrin eliciting the maximal response of 305% of resting pressure. Kinetic analysis of data indicated that the maximal response was approximately equal to that for gastrin, which suggests that the action of both peptides is mediated by the release of acetylcholine from nerve terminals. The decline in pressure at the highest pentagastrin dose was qualitatively similar to that reported for gastrin I. Glucagon significantly inhibited resting and pentagastrin-stimulated lower esophageal sphincter pressure. Resting pressure decreased 46% within 10 min of glucagon injection but by 20 min the pressure had recovered to 78% of control resting levels. Kinetic analysis showed that inhibition by glucagon was of the mixed type with a change both in affinity for and efficacy of pentagastrin. Endogenous glucagon released by i.v. infusion of alanine (0.15 g/kg in 4 min) had no effect on the resting pressure. Like secretin, glucagon apparently does not have a role in regulating the competence of the sphincter in the resting state. Its influence on the gastrin-stimulated sphincter during digestion remains to be determined.

6572 THE EFFECTS OF ELECTRICAL FIELD STIMULATION ON THE CIRCULAR MUSCLE OF THE HUMAN COLON IN VITRO.

(E.) Gunn, A. (Dept. Pharmacol., Manchester Univ., England). *Arch. Int. Pharmacodyn.* 208(2):14-18, 1974.

The effect of electrical field stimulation on the circular muscle of the human colon was studied *in vitro*. Healthy areas of distal colon removed from specimens resected for carcinoma were used in the study. No specimen was stored for a period exceeding 8 hr. The effects of antagonists on the response to acetylcholine (2.5×10^{-6} g/ml) were noted. Antagonists included atropine sulfate (10^{-7} g/ml), physostigmine sulfate (4.1×10^{-7} g/ml), hexamethonium bromide (10^{-4} g/ml), and tetrodotoxin (10^{-7} g/ml). Acetylcholine caused all specimens to contract. This response was stimulated by physostigmine and inhibited by atropine, but unaffected by tetrodotoxin or hexamethonium. The response to field stimulation was not significantly changed after the addition of hexamethonium, but was increased by physostigmine and reduced by both atropine and tetrodotoxin. An inhibitory response to field stimulation did not develop in the presence of atropine.

6573 THE EFFECTS OF METHYL METHACRYLATE VAPOR ON GASTRIC MOTOR FUNCTION.

(E.) Tansy, M. F.; Benhayem, S.; Probst, S.; Jordan, J. S. (Temple Univ. Sch. Dent., Philadelphia, Pa.). *J. Am. Dent. Assoc.* 89(2):372-376, 1974.

The effect of methyl methacrylate vapor on gastric motor activity was studied in 36 anesthetized male Sprague-Dawley rats prepared with tracheostomy tubes. A balloon and its attached tube, inserted in the stomach p.o., were filled with 3-5 ml water and were hydraulically coupled to a pressure transducer. Pressure changes produced by gastric motor activity were recorded on a strip chart recorder as functions of time. Exposure to 93.6 mg/liter/min methyl methacrylate vapor for 15 min sharply reduced both the amplitude and frequency of gastric pressure activity. This depression began within minutes of exposure and was maintained continuously during the exposure. Within 2 min after cessation of methyl methacrylate exposure, both the baseline and peak pressures returned to pre-exposure levels. Exposure to lower concentrations of vapor (1 mg/liter/min for 1 hr) produced similar but less pronounced effects; the most noticeable effect was a reduction in amplitude of the gastric pressure events which lasted for up to 20 min after cessation of exposure. Below 1 mg/liter/min, the effects of methyl methacrylate were not consistent. In a human subject, an open-tip catheter inserted in the gastric antrum enabled gastric pressure activity to be recorded upon inhalation of an uncontrolled concentration of methyl methacrylate from an open container filled with 20 ml of the liquid. A gradual decline in amplitude and frequency of intragastric pressure activity was apparent almost immediately, and the reductions became more pronounced as exposure time increased. When the vapor source was removed, activity began to increase slightly. Since a sublethal exposure to methyl methylacrylate vapor produces significant gastric motor effects in the rat, it would be prudent to determine the concentration *versus* time exposures that may constitute a hazard for occupationally exposed workers.

6574 ELECTRICAL AND MECHANICAL ACTIVITY OF CANINE STOMACH AFTER PRESERVATION.

(E.) Cook, M. A.; Kolodej, A.; Kowalewski, K. (Surg. Med. Res. Inst., Univ. Alberta, Edmonton, Canada). *Surg. Gynecol. Obstet.* 139(2):225-230, 1974.

The electrical and mechanical activity of an isolate whole canine stomach following prolonged preservatio and hypothermia and hyperbaria were measured to determine the effects of such storage on the motor activity of the stomach. The dissected stomachs were perfused rapidly through the vascular system and through the gastric lumen with 4 C Tyrode's solution They were stored immediately in a special chamber at 3 atmospheres of oxygen and 4 C. After storage periods of varying lengths, the stomachs were transferred to the perfusion chamber and connected with the perfusing blood circuitry. Measurements of electrical activity began almost at once. Except during an initial warm-up period, when a slower frequency was noted, the frequency of control waves recorded from preserved stomachs was the same as that from control stomachs, as long as the period of storage did not exceed 48 hr. The electrical and mechanical responses of these stomachs to injected pentagastrin, methacholine, and 1,1-dimethyl-4-phenylpiperazinium and to vagal stimulation suggested normal functioning of the musculature and intramural plexus layers. Stomachs preserved beyond 48 hr were in poorer conditio and little useful information could be obtained from them. This technique may prove useful for assessing a preserved organ and thereby aid in transplantation operations. It may also be useful in the study of normal motility of the stomach.

6575 INTRALUMINAL ESOPHAGEAL MANOMETRY: AN ANALYSIS OF VARIABLES AFFECTING RECORDING FIDELITY OF PERISTALTIC PRESSURES.

(E.) Stef, J. J.; Dodds, W. J.; Hogan, W. J.; Linehan, J. H.; Stewart, E. T. (Milwaukee Cty. Gen. Hosp., Wis.). *Gastroenterology* 67(2):221-230, 1974.

Bench studies, esophageal specimens (autopsy specimens suspended in fluid-filled chambers), and manometric studies in man were used to evaluate the performance characteristics of the 2 systems currently used for recording esophageal pressure: the infused-catheter system and an intraluminal transducer system. Variables studied were internal diameter of catheter, catheter length, infusion rate, amplitude, and duration of pressure complex, and also the pump system. The major cause of recording error by infusion manometry was delivery of less fluid than the setting required, sometimes as little as 15% of the rated setting. Recording accuracy was inversely related to amplitude and directly related to infusion rate and duration. For infusion manometry, pressure amplitude was recorded accurately at an infusion rate of 1.6 or 3.1 ml/min in the thoracic esophagus and 6.1 ml/min in the cervical esophagus. In the atter, peristaltic complexes were higher in ampliude (165 mm Hg) and shorter in duration (2.6 sec) han in the thoracic esophagus. The intraluminal ransducers recorded pressure accurately under all onditions tested.

SECRETION AND METABOLISM

6587 THE METABOLISM OF ^{14}C-LABELLED ESSENTIAL AMINO ACIDS GIVEN BY INTRAGASTRIC OR INTRAVENOUS INFUSION TO RATS ON NORMAL AND PROTEIN-FREE DIETS. *(E.)* Neale, R. J.; Waterlow, J. C. (London Sch. Hyg. Trop. Med., England). *Br. J. Nutr.* 32(1):11-25, 1974.

A group of rats were fed either normal or protein-free diets for 20 days. After an overnight fast, leucine, valine, lysine, and phenylalanine, all uniformly labeled with ^{14}C, were given by intragastric or i.v. infusion for 4 hr. Expired carbon dioxide was collected during infusion. Radioactivity measurements in the liver, muscle, skin, gastrointestinal tract, and the remaining carcass after infusion was complete showed no significant differences between results obtained with different amino acids. In comparing the two routes of administration, no significant difference was noted in the output of $^{14}CO_2$ expressed as a proportion of the administered radioactivity. Slightly greater radioactivity was recovered in liver and gastrointestinal tract, and less in the skin, when using intragastric infusion. A comparison of the two diets showed no difference in the proportion of dose oxidized to carbon dioxide. In rats on the protein-free diet, significantly more of the dose was recovered in the liver and gastrointestinal tract, and less in the skin. Rats receiving the protein-free diet excreted more CO_2/kg with a lower specific radioactivity. Thus, no indication of adaptive changes in the oxidation of essential amino acids was noted. However, the results are not conclusive, for under these experimental conditions the output of $^{14}CO_2$ is not a valid measure of the extent of amino acid oxidation.

6588 EFFECT OF INTRAGASTRIC ADMINISTRATION OF ALCOHOL ON THE ETHANOL CONCENTRATION AND OSMOLALITY OF PANCREATIC JUICE, BILE, AND PORTAL AND PERIPHERAL BLOOD. *(E.)* Beck, I. T.; Paloschi, G. B.; Dinda; P. K., Beck, M. (Hotel Dieu, Kingston, Canada). *Gastroenterology* 67(3):484-489, 1974.

The concentration of ethanol and the osmotic changes of biliary and pancreatic secretions in relation to those of the portal and general circulation were studied by introducing ethanol into the stomach of male dogs. Of the total dose of ethanol (0.86 ml/kg absolute ethanol as a 25% (v/v) solution), 2/3 was given as a priming dose p.o. through stomach tube. The remainder was infused at a constant rate. Pancreatic secretion was stimulated by a constant i.v. infusion of secretin (0.27 U/kg/min). The mean steady-state concentration of ethanol in the portal blood was significantly higher than in the peripheral blood and the concentration of ethanol in bile was significantly higher than in pancreatic secretion or in arterial blood, but significantly lower than in the portal blood. The data indicate that alcohol ingestion causes elevated plasma osmolality. The increase in osmolality represents the molar concentration of ethanol in portal serum, peripheral serum, biliary, or pancreatic secretion. A 51-yr-old patient with pancreatocutaneous fistula was given ethanol (125 ml of a 25% (v/v) solution), and pancreatic secretions were collected from the fistula. The ethanol concentration of the secretions and peripheral blood was similar. The osmolality of the pancreatic secretions and peripheral blood increased. These findings suggest that the pancreas secretes ethanol iso-osmotically and does not metabolize alcohol appreciably. Since ethanol penetrates the wall of the gastrointestinal tract rapidly, the liver would carry the highest concentration of ethanol, and there would be considerable enterohepatic circulation of alcohol.

6589 INHIBITION OF HEIDENHAIN POUCH PEPSIN SECRETION BY COMMERCIAL CHOLECYSTOKININ AND DUODENAL FAT IN DOGS. *(E.)* Nakajima, S.; Magee, D. F. (Creighton Univ. Sch. Med., Omaha, Neb.). *Ann. Surg.* 180(2):243-246, 1974.

In 5 unanesthetized dogs with Heidenhain pouches and separated duodenal pouches, i.v. infusion of cholecystokinin (1.0 Ivy dog U/min) produced 80.5% and 88.4% mean depression, resp., of acid and pepsin secretion stimulated by pentagastrin (1.0 μg/min i.v.). Acid response to methacholine (2.0 μg/min i.v.) was temporarily increased during cholecystokinin infusion, but the increase was not significant. Methacholine-stimulated pepsin secretion was depressed 76.5% by cholecystokinin. Similar secretory patterns were observed when duodenal pouches were irrigated with emulsified fat after pentagastrin or methacholine administration. In pentagastrin-stimulated animals, the emulsified fat irrigation caused a 32.8% mean depression of acid secretion an a 74.9% inhibition of pepsin. Acid secretion stimulated by methacholine was temporarily increased by 78.4% and pepsin secretion was inhibited by 69.3%. The results indicate that fat releases endogenous cholecystokinin from the duodenal mucosa and that cholecystokinin or duodenal fat is a potent inhibitor of gastric pepsin secretion from Heidenhain pouches.

6590 MUCOSAL DNA SYNTHESIS: A SHORT TERM INDE OF THE TROPHIC ACTION OF GASTRIN. *(E.)* Johnson, L. R.; Guthrie, P. D. (Univ. Texas Med. Sc Houston). *Gastroenterology* 67(3):453-459, 1974.

The effect of a single injection of pentagastrin (250 μg/kg) on incorporation of ^{3}H-thymidine into DNA of gastrointestinal tissues was investigated in male Sprague-Dawley rats. Animals were killed 4-24 hr after injection, and small pieces of stomach, duodenum, ileum, and liver were removed and incubat for 30 min in a medium containing 2 μC/ml ^{3}H-thymid DNA was extracted and the rate of DNA synthesis was determined by scintillation counting. Pentagastrin had no effect on DNA synthesis in the liver. In all other tissues studied, maximal stimulation occurred 16 hr after pentagastrin injection. At 16 hr, incorporation of thymidine in experimental animals was 275% of control for the stomach, 300% for the duodenum, and 480% for the ileum. Results of a single experiment with 3 different doses of pentagastrin (125, 250, and 500 μg/kg) showed that 250 μg/kg was the optimal dose for stimulation of DNA synthesis. In another series of studies, histamine (20 mg/kg) had no effect on DNA synthesis, indicating that the trophic effects of gastrin are independent of acid secretion. While trophic actions of pentagastrin on other gastrointestinal tissues have been describ previously, this is the 1st report of a trophic eff of gastrin on the ileum.

SECRETION AND METABOLISM

Stomach

03 A STUDY OF THE EFFECT OF BETAHISTINE ON GASTRIC ACID SECRETION IN MAN. *(E.)* ochran, K. M.; Allan, J. G.; Russell, R. I. (Glas-w Roy. Infirm., Scotland). *Curr. Med. Res. Opin.* 2):63-66, 1974.

istric acid secretion in 6 healthy volunteers (4 en and 2 women, aged 22-39 yr) was measured follow-g i.v. administration of betahistine, a histamine-ike drug with some histamine effects. Betahistine 1 5% dextrose solution was infused 0.5 mg/min for) min, and then 1.0 mg/min for the next 60 min; in ie subject infusion of 2.0 mg/min for 60 min was ven. These dosages were in excess of the thera-utic p.o. range of 24-48 mg/day. Gastric secre-ons, collected for each 60 min period throughout ie infusion, showed total acidity values of 3.58, 65, and 6.51 mEq, resp., for the 3 infusion rates, mpared to 3.34 mEq for the mean basal collection. ie standard 60-min acid secretion test using penta-istrin (6 μg/kg, i.m.) gave a mean of 14.99 mEq. ide effects with betahistine were headache and ushing in 5 of the 6 subjects. These results sug-est that betahistine does not increase gastric acid ecretion in normal subjects. It is concluded that icrease in acid secretion is not a factor in the production of the occasional dyspepsia reported in patients treated with betahistine for Meniere's syndrome and cerebral atherosclerosis.

6604 DUODENAL ACIDIFICATION: ROLE OF FIRST PART OF DUODENUM IN GASTRIC EMPTYING AND SECRETION IN DOGS. *(E.)* Cooke, A. R. (VA Hosp., Iowa City). *Gastroenterology* 67(1):85-92, 1974.

Gastric emptying and gastric acid secretion in response to duodenal acidification were studied in dogs with gastric and duodenal fistulas. The duodenal fistulas were placed about 5 cm distal to the pylorus. Three series of emptying studies were performed in 5 dogs. In one series, gastric emptying of a saline meal (300 ml) was studied in response to perfusion of the second part of the duodenum and distally with 0-12 mEq/hr of HCl at a constant rate of 100 ml/hr. In the second series, only the proximal 5 cm of the duodenum was acidified, and this was accomplished by diverting an acid test meal (300 ml of 40-120 mEq/liter of HCl) at the duodenal fistula. In the third series of tests, the acid meals were combined with acid perfusion so that the whole duodenum and proximal jejunum were acidified. Controls consisted of saline test meals (300 ml) and saline perfusion of the duodenum. Gastric emptying with acid in the first part of the duodenum was delayed, and the delay was about equal to perfusion of the rest of the duodenum. Acidification of the whole duodenum caused greatest delay in emptying, and the maximal effect was in response to 12 mEq/hr. Delay in gastric emptying with acid in the proximal 5 cm of the duodenum was rapid and sensitive, and occurred within 1 min and in response to 0.24-0.36 mEq of HCl. The effect of allowing acid, stimulated by histamine and pentagastrin, to bathe the first part of the duodenum was studied in 3 dogs. This was done by closing the gastric fistula and collecting from the duodenal fistula. Acidification of the first part of the duodenum inhibited (40%) pentagastrin, but not histamine-stimulated acid secretion. These studies indicate that the proximal 5 cm of duodenum is not only important for inhibition of acid secretion, but is also a powerful and sensitive site for inhibition of gastric emptying.

6605 ANTRAL AND DUODENAL ACIDIFICATION: EFFECT ON PENTAGASTRIN-STIMULATED ACID SECRETION IN THE DOG. *(E.)* Wheeler, M. H.; Prescott, R. J.; Forrest, A. P. (Dept. Clin. Surg. Univ. Edinburgh, Scotland). *Am. J. Surg.* 128(3):331-335, 1974.

For simultaneous assessment of the effect of antral acidification on pentagastrin-stimulated acid secretion by both innervated and denervated gastric mucosa, 3 dogs were each prepared with a vagally denervated fundic pouch, a vagally innervated antral pouch, and a gastric fistula. Acid secretory responses to constant i.v. infusion of pentagastrin (1.5 μg/kg/hr) were measured during antral pouch perfusion (1 ml/min) with isotonic saline at pH 7.0 for 2 hr followed by perfusion at pH 1.0 for 2 hr or *vice versa*. Gastric acid was collected from the fundic pouch with the fistula closed, from the fundic pouch with the fistula open, and from the gastric fistula. Administration of perfusate gave the same results regardless of the order in which solutions were perfused. Antral acidification at pH 1.0 did not inhibit the acid secretory response of the fundic pouch when the gastric fistula was closed, nor did it affect the acid secretion of the denervated fundic pouch or innervated main stomach when the gastric fistula was open. Diversion of acid from the duodenum had no influence on the overall level of acid secretion from the fundic pouch. Antral acidification significantly inhibited the acid output of the fundic pouch after ingestion of a meat meal (25 g/kg). Such inhibition resulted from diminished vagal gastrin release after a decrease in antral pH. Since antral acidification did not suppress pepsin secretory response to a meat meal, vagal gastrin is not an important factor in the stimulation of pepsin secretion. These results do not support the existence of an antral inhibitory hormone or inhibitory neural reflex active against pentagastrin-stimulated gastric secretion in the dog. Antral inhibition of gastric secretion is the result of diminished release or formation of endogenous gastrin.

6606 QUANTITATIVE CYTOCHEMICAL ESTIMATION OF THE EFFECT OF PENTAGASTRIN (0.005-5 pg/ml) AND OF PLASMA GASTRIN ON THE GUINEA PIG FUNDUS IN VITRO. *(E.)* Loveridge, N.; Bloom, S. R.; Welbourn, R. B.; Chayen, J. (Middlesex Hosp. Med. Sch., London, England). *Clin. Endocrinol. (New York)* 3(3):389-396, 1974.

Use of a new cytochemical approach to the bioassay of gastrin was undertaken *in vitro* on strips of fundic stomach from female guinea pigs (Hartley strain) by assessment of carbonic anhydrase activity. Exposure of tissue strips to graded concentrations of pentagastrin (0.005-5 pg/ml) at pH 7.0 produced a positive linear correlation between parietal cell activity (integrated extinction X 100) and pentagastrin concentration (log to base 10) on a calibration graph. By use of this graph, gastrin activity in diluted human plasma (1:100 and 1:1000) was extrapolated from parietal cell activity results obtained when tissue strips were exposed to the 2 plasma dilutions. The addition of 10^{-5} acetazolamide, a carbonic anhydrase inhibitor, to the reaction medium almost completely inhibited the graded response of parietal cells to increasing concentrations of pentagastrin. Maximum enhancement of carbonic anhydrase activity was found in tissues exposed for 5 min at pH 7.0. Plasma gastrin activity obtained by extrapolation was verified by separate measurements on 4 aliquots from each sample, with resulting standard deviations of less than ±0.7 for each sample. A comparative study on 5 plasma samples showed that radioimmunoassay and the cytochemical assay gave comparable results. The cytochemical assay allows measurement of pentagastrin to a level of 0.005 pg/ml (6.6 X 10^{-15} M), and gastrin-like activity in human plasma at concentrations equivalent to or less than 0.05 pg/ml (2.3 X 10^{-14} M) of human gastrin (synthetic 17 amino acid gastrin).

6607 EFFECT OF HISTAMINE H-RECEPTOR BLOCKADE ON FASTING SERUM GASTRIN AND FASTING GASTRIC ACID SECRETION IN THE DOG. *(E.)* Barbezat, G. O.; Daniel, M.; Bank, S.; Grant, B.; Vinik, A. (Groote Schuur Hosp., Cape Town, South Africa). *Nature (Lond.)* 249(5458):666-668, 1974.

To investigate the effects of burimamide, an antagonist of histamine H_2-receptors, on gastric acid secretion and blood gastrin levels under basal conditions, 2 mongrel dogs with gastric fistulas and 2 control dogs were studied 3 months after surgery. All animals were fasted for 16 hr before each experimental procedure. Burimamide injection (8 mg/kg i.v.) resulted in minimal variations in serum gastrin concentrations with no significant differences from basal levels of 40-80 pg/ml. After a small decrease, gastric acid secretion increased slightly 30-60 min after burimamide, but this was small in terms of acid output, reaching a maximum of 1.20 and 0.72 mEq/15 min over basal levels in the 2 dogs. The results in this study show that serum gastrin levels are not altered by i.v. burimamide given to fasting dogs. There is no evidence to support the concept that H_2-receptor antagonists inhibit gastric acid secretion by acting outside the parietal cell. However, it is possible that histamine and gastrin ct on different receptors on the same cell. Since urimamide has a short duration of action in both ogs and pigs, the late rise in gastric acid secreion following burimamide may result from rebound ollowing withdrawal of the inhibitor. This reound phenomenon can be clinically relevant if it ccurs when H_2-receptor antagonists are used theraeutically in man.

608 THE EFFECT OF BETA-ANDRENERGIC BLOCKADE UPON GASTRIC ACID SECRETION AND GASTRIN ECRETION DURING HYPOGLYCAEMIA BEFORE AND AFTER VAOTOMY.

(E.) Kronborg, O.; Pedersen, T.; Stadil, .; Rehfeld, J. F. (Bispebjerg Hosp., Copenhagen, enmark). *Scand. J. Gastroenterol.* 9(2):173-176, 974.

he effect of propranolol on the gastric acid and erum gastrin responses to hypoglycemia were investiated in a double-blind trial involving 29 patients 10 with intact gastric vagal innervation, including with duodenal or prepyloric ulcers; 9 with duodenal r prepyloric ulcers who had been subjected to vagoomy and drainage 10 days previously; and 10 with uodenal prepyloric ulcers who had been subjected to agotomy and drainage 2 to 3 months previously). All atients had two insulin tests separated by an interal of 1 or 2 days. Two hr prior to each test the ubjects were given a placebo or a tablet containing 0 mg of propranolol. Propranolol suppressed the seum gastrin concentrations in the fasting state and uring hypoglycemia in the ulcer patients both before nd after vagotomy. The fasting acidity was suppressd in the vagotomized patients and increased in the ntact patients; the insulin-activated acidity was educed in both groups. Depression of the gastrin evels by propranolol occurred 15 to 45 min before he depression of gastric acidity. The depression of erum gastrin levels by propranolol may be due to a eta-blockade of an adrenergic stimulation of the anrum.

609 EFFECT OF RESERPINE ON SERUM GASTRIN CONCENTRATION AND ON MUCOSAL AMINES AND AMINO CID DECARBOXYLASE ACTIVITIES IN RAT STOMACH.

(E.) akanson, R.; Liedberg, G.; Rehfeld, J. F.; Sundler, .; Ericson, L. E. (Dept. Pharmacol., Univ. Lund, Sween). *J. Pharmacol. Exp. Ther.* 189(3):603-615, 1974.

eserpine is known to reduce gastric mucosal 5-hydroxyryptamine and histamine and to stimulate acid secreion. The present study on 1400 male Wistar rats hows that this effect of reserpine (0.1-25 mg/kg) in he stomach of the rat is independent of an intact xtrinsic autonomic innervation, as seen in 160 vaotomized and 17 sympathectomized rats, and probably esults from a direct action on the amine storage echanisms. Reserpine failed to affect pyloric histiine decarboxylase but caused a short-lasting reducion in oxyntic histidine decarboxylase activity ollowed by a progressive rise in the enzyme activity ack to normal or even supra-normal values. This haracteristic pattern was observed in both vagotomzed and unoperated rats. The reduction of enzyme ctivity was interpreted as the result of enzyme leakage from the histamine-producing cells of the oxyntic mucosa or of specific inhibition of histidine decarboxylase synthesis. The increase in enzyme activity was prevented by antrectomy, performed on 45 rats, suggesting that the activation was a result of reserpine-induced gastrin release. This assumption was supported by the finding of an increase in serum gastrin concentrations coinciding in time with the enzyme activation and possibly of increased acid production.

6610 EFFECT OF INTRAVENOUSLY ADMINISTERED CALCIUM ON SERUM GASTRIN AND GASTRIC SECRETION IN MAN.

(E.) Reeder, D. D.; Becker, H. D.; Thompson, J. C. (Univ. of Texas Med. Branch, Galveston). *Surg. Gynecol. Obstet.* 138(6):847-851, 1974.

Serum gastrin responses to i.v. infusion of calcium were determined in 21 healthy volunteers, 12 patients with duodenal ulcers, and 5 patients who had undergone total gastrectomy and who had residual Zollinger-Ellison tumors. During a 1 hr basal period, normal saline solution was infused i.v. at the rate of 50 ml/hr. During the next 4½ hr, calcium gluconate (4 mg/kg) was infused at 50 ml/hr; in the patients with the Zollinger-Ellison syndrome, the calcium infusion lasted 4 hr. Additionally, an i.v. loading dose of calcium (4 mg/kg) was injected slowly during the first 30 min of calcium infusion. In normal subjects, calcium infusion doubled the mean basal acid output, whereas in patients with duodenal ulcer disease, the increase in gastric output was about 250%. Patients with a duodenal ulcer secreted more than 5 times as much acid as did normal persons. Serum gastrin concentrations rose 34% over basal in normal persons, 94% in those with a duodenal ulcer, and 55% in patients with Zollinger-Ellison tumors after total gastrectomy. The integrated gastrin output of the patients with a duodenal ulcer was more than double that of controls and less than ½ that of the patients with the Zollinger-Ellison syndrome. The mechanism by which hypercalcemia induces elevated serum gastrin levels is not clear. While calcium appears to serve as a coupling factor between excitation and secretion at many endocrine glands, it is not known if the gastrin releasing mechanism acts similarly.

6611 GASTRIC ACID RESPONSES TO ANTRAL APPLICATION OF SOME AMINO ACIDS, PEPTIDES, AND ISOLATED FRACTIONS OF A PROTEIN HYDROLYSATE.

(E.) Elwin, C. E. (Karolinska Inst., Stockholm, Sweden). *Scand. J. Gastroenterol.* 9(3):239-247, 1974.

The stimulatory effect of single amino acids and of some peptides when applied in the antrum has been studied. Mongrel dogs were provided with either Heidenhain or Pavlov pouches. Amino acids with 2 or 3 carbons (glycine, β-alanine) demonstrated secretagogue activity. This activity decreased with methylation of the amino group (sarcosine) or with a change in its steric location (α-alanine). Usually di- or tri-peptides derived from glycine and alanine were less active. Glycyl-glycine proved an exception to this generalization. An additive effect was noted when 2 amino acids were concomitantly introduced to the antral pouch. In no instance of combined administration was a synergistic effect demonstrated. Peptides of a protein hydrolysate were separated by dialysis, ultrafiltration, or gel filtration. The potency of the isolated fraction to stimulate gastric secretion was related to molecular size of the peptide and the presence of free amino acids. The smaller peptides and those having more free amino acid groups had the most pronounced effects. The stimulation of acid secretion by these compounds is most likely due to release of gastrin, since it has been shown that feeding increases serum gastrin levels.

6612 EFFECT OF GLUCAGON ON GASTRIC SECRETION IN FISTULA CHICKENS.

(E.) Burhol, P. G. (Ulleval Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(4):411-414, 1974.

The effect of i.v. injection of glucagon (25, 50, and 100 μg/kg) on basal gastric secretion was studied in 8 unanesthetized chickens with gastric fistulas. Each dose was given once to each chicken on separate days. Gastric juice samples were collected for 90 min and analyzed in 15-min aliquots. Glucagon produced a significant and dose-dependent fall in the gastric secretion rate. Concomitantly, glucagon caused a significant and dose-dependent decline in the mean gastric H^+ output from a basal level of 0.27 to 0.04 mEq/15 min. The mean pepsin output dropped significantly from a basal level of 2.0 to 0.6 mg/15 min only with the highest dose of glucagon. The ratio of pepsin to H^+ rose significantly after glucagon administration, indicating that more pepsin is secreted/U of H^+ secretion after glucagon injection than before. The prompt gastric inhibition following glucagon administration suggests a direct action of glucagon on the gastric mucosa. It is not yet known if the recently discovered glucagon-like substances released from the gut of mammals and birds affect gastric secretion. If they do, it is possible that glucagon participates in the physiological regulation of gastric secretion.

6613 ACTIONS OF METIAMIDE, AN H_2-HISTAMINE RECEPTOR ANTAGONIST, ON GASTRIC H^+ AND PEPSIN SECRETION IN DOGS.

(E.) Gibson, R.; Hirschowitz, B. I.; Hutchison, G. (Dept. Med., Univ. Alabama, Birmingham). *Gastroenterology* 67(1):93-99, 1974.

Metiamide, a thiourea analog of histamine, is an antagonist of the gastric histamine receptor (type H_2). At i.v. doses of 0.2 and 0.5 mg/kg/hr, it was a potent competitive inhibitor of H^+ secreted by dogs in response to step-doses of histamine (5-100 μg/kg/hr), pentagastrin (0.1-10 μg/kg/hr), and bethanechol (20-120 μg/kg/hr). At a dose of 2.5 mg/kg/hr, metiamide almost completely inhibited histamine stimulation (acting uncompetitively), but had a less potent effect on pentagastrin and 2-deoxyglucose (100 mg/kg) stimulated H^+ secretion. By contrast, during metiamide administration, pepsin secretion stimulated by the cholinergic stimuli, bethanechol and 2-deoxyglucose, was further increased, while H^+ secretion was inhibited. All stimuli for both H^+ and pepsin exhibited dose-reversal effects. The mechanism of this inhibitory effect of even potent stimuli is not known. The fact that histamine in small doses does stimulate pepsin secretion suggests that the histamine receptor may be a site with a very low dose-reversal point. The H_2 receptor, on the parietal cell, has a high dose-reversal point. The dose-reversal point for bethanechol (i.e. above 80 μg/kg/hr) is well below the maximum secretory capacity of the gastric mucosa. Metiamide shifts this point to the right to the extent that the whole curve of the dose response is shifted, but does not alter the essential features of dose reversal, which is analogous to inhibition of enzyme reaction by an excess of substrate, rather than to feedback inhibition by a product of the enzyme action.

6614 COMPARISON OF VAGAL AND MEAT STIMULATION OF GASTRIC ACID SECRETION AND SERUM GASTRIN IN CATS.

(E.) Blair, E. L.; Grund, E. R.; Reed, J. D.; Shaw, B.; Wilkinson, J. (Dept. Physiol., Univ. Newcastle upon Tyne, England). *J. Physiol. (Lond.)* 240(2):33P-34P, 1974.

In chloralose-anesthetized cats with the stomach divided into antral and fundic pouches, the concentration and amount of serum gastrin, as well as the amount of gastric acid, secreted during vagal excitation were compared with values during stimulation by meat-extract instillation into the antral pouch. Acid secretion and gastric mucosal blood flow were measured by electrometric titration and amidopyrene clearance, resp., and serum gastrin by radioimmunoassay. In 4 animals vagal stimulation preceded meat-extract presentation while in 4 others the order was reversed. During vagal excitation, both the mean acid secretion (54 μEq/3 min) and mucosal blood flow (10.7 ml/3 min) were significantly greater than during meat stimulation (12.0 μEq/3 min and 3.2 ml, resp.). By contrast, the mean serum gastrin concentration was significantly less during vagal stimulation (35.0 pg/ml) than with meat extract (132.0 pg/ml). There was no significant difference in the mean total serum gastrin during the 2 types of stimulation. Present findings indicate vagal stimulation produces significantly greater acid secretion than can be attributed to the action of gastrin alone. Probably, action of the vagus on gastric acid secretion is not limited to its role in the release of gastrin.

6615 MECHANISM OF THEOPHYLLINE STIMULATION OF ACID SECRETION BY FROG GASTRIC MUCOSA.

(E.) High, W. L.; Hersey, S. J. (Dept. Physiol., Emory Univ., Atlanta, Ga.). *Am. J. Physiol.* 226(6):1408-1412, 1974.

A study was undertaken to further identify the mechanism of theophylline action as a stimulator of both hydrogen ion secretion and respiration by *in vitro* frog gastric mucosa, particularly with regard to its substrate mobilizing capability. The dose-response curves for the parameters of acid secretion and respiration were strikingly similar. Control experiments indicated that the use of a carbonate- or bicarbonate-free medium for measuring respiration does not significantly alter the relation between respiration and acid secretion. Optical measurements of the redox state of the respiratory chain components showed an increased level of cytochrome reduction in response to theophylline. Kinetic measurements showed that the cytochrome reduction occurs prior to the acid secretory response to theophylline. Thus theophylline acts, probably by cyclic AMP, to mobilize endogenous metabolic substrates as a primary mechanism of action. Measuring the respiratory quotient before and after theophylline stimulation showed a significant decrease in respiratory quotient which could not be explained by simply the observed increase in oxygen consumption. Thus it is proposed that theophylline acts by mobilizing endogenous fatty acids and that the oxidation of the fatty acids plays a specific and direct role in the secretion of acid by this tissue.

6616 THE INFLUENCE OF VITAMINS, AMINO ACIDS AND FATTY ACIDS ON THE HYDROCHLORIC ACID SECRETION OF THE ISOLATED GASTRIC MUCOSA. *(E.)*

Pokrovsky, A. A.; Levin, L. G.; Gapparov, M. M. (Inst. Nutr., Moscow, USSR). *Int. J. Vitam. Nutr. Res.* 43(2):233-241, 1973.

The secretion rate, the level of nicotinamide adenine dinucleotide phosphate fluorescence, and the oxygen consumption of the isolated gastric mucosa of frogs (*Rana radibunda*) were measured in the presence of different nutrients, substrates, and inhibitors of a respiratory chain. Of the 19 amino acids tested, only glutamic acid (10 mM) and l-methionine (100 μM) had a distinct stimulating effect on H^+ secretion. Unsaturated fatty acids (linoleic and arachidonic acids) had a stimulating effect at 1 mM, whereas a saturated fatty acid (palmitic acid) did not have a marked influence in H^+ secretion in the gastric mucosa. Among vitamins, thiamine and biotin (250 μM) had a marked stimulating effect; vitamin D and vitamin A (10-500 μg/ml) inhibited H^+ secretion. The inhibitory effect of vitamin A was less pronounced. These results are useful in considering the mechanism of chemical regulation of the acid secretion of the gastric mucosa. Certain nutrients appear to have direct regulatory action on the HCl secretion only after their absorption in the blood during the second phase of the HCl secretion. In all cases, the stimulation of H^+ secretion is closely connected to the oxidative metabolism and the redox level of pyridine nucleotide in the gastric mucosa. Nutrients may exert a stimulating effect on HCl secretion in two ways: first, they may be used as substrates (glutamic acid, fatty acids and Krebs cycle substrates) for biological oxidation. Second, the nutrients (thiamine and biotin) may participate in the process of HCl synthesis as cofactor.

6617 ADENYL CYCLASE STIMULATION BY ASPIRIN IN RAT GASTRIC MUCOSA. *(E.)*

Mangla, J. C.; Kim, Y. M.; Rubulis, A. A. (Monroe Community Hosp., Rochester, N.Y.). *Nature (Lond.)* 250(5461):61-62, 1974.

The effects of aspirin on gastric mucosal adenyl cyclase were studied in male Holtzman rats given aspirin p.o. by stomach tube (150-300 mg/kg homogenized in 1% methyl cellulose). Animals were sacrificed after 5 min to 5 hr. At the highest dose, stimulation of adenyl cyclase was apparent within 5 min of aspirin administration. Enzyme stimulation was maximum after 4 hr and was significantly different from the control value. At the lowest dose, aspirin gave comparable results 30 min after p.o. administration. In *in vitro* studies, 0.3, 0.6, 0.9, 1.2, or 1.8 mg aspirin/0.38 ml reaction mixture was added to gastric mucosal homogenate from 24 rats. There was a direct correlation between aspirin concentration and degree of adenyl cyclase activity, which increased linearly with concentrations up to 1.8 mg aspirin in 0.38 ml reaction mixture. If cyclic AMP stimulates gastric acid secretion, stimulation of adenyl cyclase by aspirin may explain mucosal injury associated with aspirin consumption. Should cyclic AMP inhibit gastric secretion, this may be another explanation for the hypoacidity seen after injury by aspirin. It is also possible that adenyl cyclase stimulation by aspirin quickly exhausts ATP stores, thus causing mucosal injury.

6618 PLASMA PROTEIN SHEDDING BY THE CANINE OXYNTIC GLANDULAR MUCOSA INDUCED BY TOPICAL APPLICATION OF SNAKE VENOMS AND ETHANOL. *(E.)*

Davenport, H. W. (Dept. Physiol., Univ. Michigan, Ann Arbor). *Gastroenterology* 67(2):264-270, 1974.

In 15 female dogs, a single irrigation of an oxyntic glandular mucosa pouch of the stomach with dilute solution (0.5 mg/ml) of lyophilized venom of the hooded cobra (*Naja naja*) broke the gastric mucosal barrier, as shown by the large increase in Na^+ output, but shedding of plasma did not occur. Twenty to 40 days later, a similar irrigation caused a very large shedding of plasma through the mucosa (over 30 ml/30 min). The degree of shedding declined during the next 30 days, with various amounts of residual plasma shedding still occurring. At essentially zero response, irrigation with cobra venom still broke the gastric mucosal barrier. Treatment for 7-14 days with prednisolone tertiary butylacetate (1 mg/kg/day, i.m.) attentuated but did not abolish plasma shedding with venom irrigation. Ethanol irrigation (30% v/v) also caused plasma shedding whether or not the mucosa had previously shed plasma in response to venom irrigation. A dilute solution (0.5 mg/ml) of lyophilized venom from Russell's viper did not induce shedding by itself but did so after irrigation with ethanol. Mucosal irrigation with numerous other foreign proteins (egg albumin, conalbumin, milk proteins, gluten fragments inducing gluten enteropathy, trypsin, urease, and papain) combined with various barrier breakers (digitonin, acetic acid, urea, salicylic acid, and cobra venom) did not achieve induction of plasma shedding. Present results do not substantiate the theory involving the following series of events: (1) breaking of gastric barrier by venom; (2) production of immune response by antigen acting venom; (3) release of histamine as part of immune response; and (4) induction of reactions including plasma shedding by histamine.

6619 EFFECT OF ORAL ADMINISTRATION OF DEGRADED CARRAGEENAN ON THE INDUCTION OF GASTRIC ULCERS IN RATS TREATED WITH GLUCOCORTICOIDS.

(E.) Emerson, L.; Kerkut, G. A. (Dept. Physiol. Biochem., Univ. Southampton, England). *J. Comp. Pathol.* 84(2): 151-160, 1974.

Female Wistar rats, fasted through the experimental period, were injected s.c. with fluocortolone or difluocortolone trimethyl acetate (10, 25, or 50 mg/kg/day) for 4 days or with prednisolone or difluocortolone (25 or 50 mg/kg/day) for 4 days. To determine its inhibitory effect on ulcerogenicity of the glucocorticoids, degraded carrageenan was administered p.o. by intubation (400 mg/kg) immediately prior to the daily injection of one of the glucocorticoids. Prednisolone was the least potent ulcerating agent, followed by increasing levels of ulcerogenicity with fluocortolone, difluocortolone, and difluocortolone trimethyl acetate. The severity of ulceration was dose-related. Carrageenan pretreatment significantly reduced ulcer severity in rats receiving fluocortolone, difluocortolone, and difluocortolone trimethyl acetate; severity of ulceration produced by prednisolone was not affected by carrageenan. Histologically, mucosal ulceration in carrageenan-treated rats was more superficial than in rats given the glucosteroids alone. Although erosion was extensive in some cases, the lesions never penetrated the muscularis mucosa. The exact mode of action of degraded carrageenan remains to be elucidated.

6620 HYPOTHERMIA IN RESTRAINT-INDUCED GASTRIC ULCERS IN PARABIOTIC RATS.

(E.) Tran, T. A.; Gregg, R. V. (Univ. Louisville Sch. Med., Ky.). *Gastroenterology* 67(2):271-275, 1974.

Colonic body temperatures of adult female ARS Fischer 344 rats were monitored in restrained and unrestrained animals as well as in restrained and unrestrained parabiosed rat pairs. Environmental temperature was 22 C. Restrained animals, whether single or parabiosed, all developed macroscopic ulcerations and showed a mean drop in body temperature of 6.3 C after 24-30 hr of immobilization from initial readings of 37.3 C. Body temperatures of unrestrained parabiosed rats that ulcerated macroscopically within 28-30 hr dropped 4.5 C. However, body temperatures of unrestrained rats that developed no ulcers or only microscopic ulcers decreased only 3.5 C by the 9th hr of restraint, and gradually returned to control values by the 12th hr. These results clearly demonstrate hypothermia in rats subjected to restraint. Whether the hypothermia in restrained and unrestrained parabiosed rats is secondary to factors causing gastric mucosal alterations, or plays a causative role, is currently under investigation.

6621 PROPHYLAXIS BY VITAMIN C IN STARVATION INDUCED RAT STOMACH ULCERATION.

(E.) Cheney, C. C.; Rudrud, E. (Dept. Psychol., Utah State Univ., Logan). *Life Sci.* 14(11):2209-2214, 1974.

Long-Evans female rats were randomly divided into 4 groups of 20 each: (1) controls with free access to food and water but no vitamin administration; (2) starved; (3) starved with administration of deactivated ascorbic acid (6 g/200 ml drinking water); or (4) starved with administration of active ascorbic acid. The vitamin was also provided for 8 days prior to starvation. Sacrifice occurred after 6 days or when weight loss was 30%. Control animals developed no ulcers and animals receiving active ascorbic acid showed only 4 ulcers with mild or moderate lesions. In contrast, group 2 rats had 20 ulcers, of which 16 were severe. Rats receiving deactivated ascorbic acid demonstrated 17 ulcerations: 6 severe, 6 moderate, and 5 mild. These results strongly suggest that active L-ascorbic acid taken p.o. is effective in protecting the animals against starvation-induced ulceration. It is not clear whether the tissues were at saturation and whether the protection would last indefinitely.

6622 QUANTITATIVE HISTOLOGIC DISTRIBUTION OF ADENOSINE-3',5'-MONOPHOSPHATE IN THE RAT STOMACH. IMPROVED PROCEDURE FOR THE LUMINESCENCE ASSAY.

(E.) Glick, D.; Katsumata, Y.; von Redlich, D. (Stanford Univ. Med. Sch., Calif.). *J. Histochem. Cytochem.* 22(6):395-400, 1974.

Procedural improvements in the luminescence method for determining adenosine-3',5'-monophosphate (cAMP) in submilligram samples were developed for purposes of technical simplification, time saving, and increased analytical precision. The improved method has been applied to the determination of the quantitative histologic distribution of cAMP in the body of the glandular stomach of fed and fasted Sprague-Dawley male rats. In fasted rats, a sharp peak in cAMP concentration (0.12 pmole/μg protein-nitrogen, about 3.3 pmoles/mg wet weight) was noted in the parietal mucous neck cell zone. The values fell rapidly to about ½ peak value in the chief cell region and remained in this range into the muscle layer. In fed rats, second and third peaks appeared in the chief cell and muscle zones, each about 10% less than the first peak. The histologic position and height of the first peak did not change significantly from that in the fasted state. Homogenates of glandular stomach of fed rats had cAMP values in the range 1.9 to 2.4 pM/mg wet weight. Literature findings that histamine formed in the chief cell region may be available to the parietal cell for stim-

lation of acid section would be compatible with the
AMP concentration (0.12 pM/μg protein-nitrogen,
bout 3.3 pM/mg wet weight) was noted in the pa-
rease of cAMP concentration in the stomach muscle
n the fed, compared with the fasted rat, may be re-
ated to the role of cAMP in motility of the organ.

6623 SEPARATION OF PROLIFERATIVE AND MATURE CELLS IN STOMACH, JEJUNUM AND COLON OF RAT. *(E.)* Schmidt, M.; Lipkin, M. (Mem. Sloan Kettering Cancer Ctr., New York, N.Y.). *Proc. Soc. Exp. Biol. Med.* 146(3):836-839, 1974.

A tissue-planing method has been modified in such a way as to allow mature, well-differentiated cells lining the surface of the stomach and the distal colon to be separated from immature cells in the deeper layers of the mucosa. The upper 6 cm of jejunum or terminal 6 cm of colon were removed from male CFE rats. A segment of jejunum was mounted on a lucite block, causing it to open lengthwise and allowing the villi to protrude upward. A sliding micrometer-mounter razor blade moved horizontally across the tissue to cut off the villus layers. For separation of cells in descending colon and stomach segments, new tissue supporting blocks were necessary to stretch the tissues enough to eliminate diagonal folds and the gastric rugae. Incorporation of thymidine-^{3}H-methyl into DNA was greatest in cells in the area below the surface of the mucosa occupied by proliferating cells, at 1 hr after injection. Labeled cells then moved outward toward the surface of the mucosa where the amount of label increased at 24 and 72 hr. Thymidine kinase activity fell markedly as cells migrated from crypt to villus, and in colon and stomach thymidine kinase activity also decreased in migrating and differentiating cells. By enabling separation of proliferating and differentiating gastrointestinal cells in different regions, this method will permit the study of factors influencing mechanisms of carcinogenesis and other proliferative and differentiation-specific characteristics of the cells.

SECRETION AND METABOLISM

Pancreas

6637 THE KINETICS OF PANCREATIC AMYLASE SECRETION AND ITS RELATIONSHIP TO VOLUME FLOW AND ELECTRICAL CONDUCTANCE IN THE ANAESTHETIZED CAT.
(E.) Greenwell, J. R.; Scratcherd, T. (Univ. Newcastle Med. Sch., Tyne, England). *J. Physiol. (Lond.)* 239(3):443-457, 1974.

Experiments were designed to relate the kinetics of amylase secretion to volume flow and the transverse electrical conductance across the pancreas. Enzyme secretion in response to short duration vagal stimulation or to rapid i.v. injections of cholecystokinin-pancreozymin or gastrin, or to intra-arterial injections of acetylcholine is a function of the volume of juice secreted and not primarily a function of time. Regardless of the rate of background, secretin stimulated flow of water and electrolyte. The output of amylase in response to each stimulus occurred in a constant volume of about 15 drops (0.5 ml). Because amylase secretion occurs in this constant volume, it is suggested that the secretion is due to the rapid secretion of enzyme into the duct system from the acini, and subsequent stimulation of water and bicarbonate secretion by secretin which washes the enzyme from the duct system. An increase in the electrical conductance occurs across the tail of the pancreas when enzyme secretion is stimulated. This increased conductance has two components: an early peak associated with the extrusion of enzyme from the acinar cell, and a later peak which is probably due to vasodilatation. Atropine had no effect on either the enzyme secretion or the conductance record when the stimulant was cholecystokinin-pancreozymin. Atropine blocked enzyme secretion and both peaks of the conductance record in response to acetylcholine stimulation. For vagal stimulation atropine blocked enzyme secretion and abolished the early phase of the conductance record. It had no effect on the later peak, indicating an atropine-resistant vasodilation of the pancreatic vessels. When the vagus is stimulated on a background of submaximal electrolyte secretion caused by the i.v. infusion of gastrin, the volume rate of secretion and the rate of amylase secretion follow a similar time course. The maximal volume response occurred between 7 Hz and 15 Hz, and the maximal amylase output impulse occurred at 5 Hz.

6638 PANCREATIC SECRETION IN RESPONSE TO JEJUNAL FEEDING OF ELEMENTAL DIET. *(E.)*
Cassim, M. M.; Allardyce, D. B. (Dept. Surg., Univ. British Columbia, Vancouver, Canada). *Ann. Surg.* 180(2):228-231, 1974.

A study was made in dogs to determine the effect of elemental and blenderized ward diets, infused throug a jejunostomy, on pancreatic secretion. The dogs were prepared with Thomas cannulae in the stomach, duodenum and proximal jejunum. The main pancreatic duct was cannulated and the catheter allowed to lie in the duodenum. A stable 50% of maximum pancreatic secretory response was obtained by infusion of secretin (3 μg/kg) and pancreozymin-cholecystokinin (6 μg/kg) before tube feeding. Jejunostomy feeding with the elemental diet significantly increased the volume and bicarbonate content of pancreatic secretion above the 50% of maximum plateau, but the protein content of pancreatic juice decreased. Unlike the elemental diet the blenderized diet also increased the protein content of the pancreatic secretion. Although the elemental diet infused through a jejunostomy did not "rest" the pancreas, it may be advantageous for use in feeding patients with acute pancreatitis.

6639 DIRECT AND INDIRECT EFFECTS OF NICOTINE ON RABBIT PANCREATIC SECRETION. *(E.)*
Solomon, T. E.; Solomon, N.; Shanbour, L. L.; Jacobson, E. D. (Univ. Texas Sch. Med., Houston). *Gastroenterology* 67(2):276-283, 1974.

In vitro and *in vivo* preparations of rabbit pancreas were used to determine whether nicotine acts directly on the pancreas to inhibit exocrine secretion, or whether this inhibition is mediated by release of endogenous substances. Very high nicotine concentrations (1.6 mg/ml in the bathing fluid) were required to produce significant declines in *in vitro* secretory volume and bicarbonate output. There was concomitant depression of cellular ATP levels. These direct *in vitro* effects represent nonspecific toxic effects on cell metabolism since much lower plasma concentrations of nicotine inhibited secretion *in vivo* without depressing tissue metabolism. In *in vivo* studies, i.v. infusion of nicotine (100, 200, 400 μg/kg/hr for 1 hr) inhibited flow rate and bicarbonate concentration and output in a dose-dependen fashion. At the 2 higher doses, the volume and bicarbonate output after nicotine infusion were significantly above the prenicotine values. These results suggest that nicotine is not the final mediator of the inhibitory effects of smoking on pancreatic secretion. Norepinephrine (2 or 4 μg/kg/min i.v., for 30 min) inhibited secretory flow and bicarbonate output. Mean systemic arterial blood pressure rose rapidly and then declined slowly to a value 11 mm Hg higher than before norepinephrine administration. Epinephrine (2 μg/kg/min i.v.) produced similar effects. Phenoxybenzamine (1 mg/kg) infused over 20 min decreased blood pressure, and significantly increased water and bicarbonate secretion. After a 40-min stabilization period after phenoxybenzamine infusion, neither nicotine (200 μg/kg/hr, 1 hr) nor norepinephrine (4 μg/kg/min for 30 min before or after nicotine) had any effect on pancreatic secretion. The results support the role of catecholamines in nicotine-induced inhibition of pancreatic exocrine secretion of water and bicarbonate. The previously observed failure of phenoxybenzamine to prevent inhibition of pancreatic secretion evoked by ethanol indicates that phenoxybenzamine produced specific blockade to the effects of norepinephrine and nicotine. Apparently, nicotine depresses pancreatic secretion through adrenergic mediators. This indirect action of nicotine explains the disparity between the *in vitro* and *in vivo* results and suggests a possible relation between the sympathetic nervous system and the pancreas, at least in terms of the pathogenesis of duodenal ulcer in the cigarette smoker.

SECRETION AND METABOLISM

Hepatobiliary Tract

6651 INFLUENCE OF PORTACAVAL SHUNT ON BILE FORMATION IN THE RAT. *(E.)* Prandi, D.; Dumont, M.; Erlinger, S. (Beaujon Hosp., Clichy, France). *Eur. J. Clin. Invest.* 4(3):197-200, 1974.

Bile flow and bile acid secretion were measured in male Charles River rats 21-28 days after a portacaval shunt and in sham-operated and normal animals. Bile flow was significantly lower (6.65 ± 0.36 μl/min/100

g) in the shunted rats than in the sham-operated animals (8.21 ± 0.21 μl/min/100 g). Bile acid secretion was not significantly different in shunted rats (0.27 ± 0.03 μM/min/100 g) and sham-operated rats (0.26 ± 0.02 μM/min/100 g). During bile acid infusions (sodium taurocholate, 0.2-0.7 μM/min/100 g), there was a linear relation between bile flow and bile acid excretion in both groups of animals. The slope of the relation was similar, suggesting that the osmotic activity of the bile acids was not modified in the shunted animals. The bile acid-independent flow, estimated by the extrapolation of this relation to a zero bile acid excretion, was significantly lower in rats with a portacaval shunt (5.20 ± 0.40 μl/min/100 g) than in sham-operated controls (6.50 ± 0.30 μl/min/100 g). Liver weight was significantly lower in shunted than in sham-operated animals, and there was a parallel decrease of liver weight (-17%) and of the bile acid-independent flow (-22%). No difference was found between the sham-operated rats and the normal rats. It is concluded that the decreased bile flow in animals with a portacaval shunt was due to the decrease in the bile acid-independent flow. Since bile acid secretion rate remained unchanged, the secretion of bile acids and the bile acid-independent flow may be regulated by separate mechanisms.

6652 A COMPARISON BETWEEN THE BILE ACID CONCENTRATION AND THE INORGANIC CATION-ANION DIFFERENCE IN DOG BILE. *(E.)* Kutz, K.; Paumgartner, G.; Egger, G.; Preisig, R. (Dept. Clin. Pharmacol., Univ. Berne, Switzerland). *Gastroenterology* 67(1): 135-141, 1974.

The relation between the difference of inorganic cations [$Na^+ + K^+$] and anions [$Cl^- + HCO_3^-$] and enzymatically determined bile acids in bile was studied in the unanesthetized dog equipped with a Thomas duodenal cannula. Bile composition was analyzed during biliary drainage with and without i.v. infusion of sodium taurocholate (12-72 μEq/min). Similar investigations were carried out after administration of choleretic agents such as secretin (0.05-0.2 U/min), lypressin (0.5 U/kg), ouabain (0.02 mg/kg), and insulin (1 U/kg). Over a wide range of bile acid concentrations (approximately 50 to 150 mEq/liter), the electrolyte difference yielded a satisfactory approximation of bile acid content in dog bile. At low bile acid concentrations (below 50 mEq per liter), however, the cation-anion difference overestimated bile acids.

6653 EFFECT OF PHENOBARBITAL TREATMENT ON TOTAL AND INDIVIDUAL BILE ACIDS IN THE SERUM AND LIVER OF NORMAL RATS AND RATS WITH CHOLESTASIS INDUCED BY α-NAPHTHYLISOTHIOCYANATE. *(Ger.)* Leinweber, W.; Muhlenkamp, H.; Erb, W. (Ctr. Internal Med., Univ. Frankfurt/Main, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:955-956, 1973.

Bile acids were determined in the serum and livers of female Sprague-Dawley rats given phenobarbital (50 mg/kg i.p. twice a day for 8 days) and on rats given phenobarbital and α-naphthylisothiocyanate (ANIT; 100 mg/kg p.o.). Phenobarbital significantly decreased total serum bile acids from 3.7 to 1.8 μg/ml, largely by decreasing cholic acid concentrations. Significant decreases also occurred in deoxycholic and β-methylcholanic acids. Total bile acids also decreased significantly in the liver (from 95 to 66 μg/g), but the only bile acid which decreased significantly was deoxycholic acid. A comparison of the relative percentages of individual bile acids revealed that phenobarbital decreases cholic acid and increases chenodeoxycholic acid levels in both serum and liver. The decrease in bile acid levels may be due to an increase in their excretion in the bile and stools. Administration of ANIT alone produced large increases in total bile acids, cholic and chenodeoxycholic acids, and particularly in β-methylcholanic acid. Phenobarbital pretreatment caused an additional increase in total serum bile acids with a decrease in cholic acid, significant increases in chenodeoxycholic and α-methylcholanic acid, and a slight increase in β-methylcholanic acid. In contrast to findings in humans with cholestasis, phenobarbital did not reduce serum bile acids in rats with ANIT-induced cholestasis. The increases in chenodeoxycholic, α-methylcholanic, and β-methylcholanic acids in ANIT-induced cholestasis suggests that bile acids can be synthesized without 12-α-hydroxylation. It is suggested that normal rats can control this increase by excreting increased quantities of bile acids.

6654 STUDIES ON BILE SECRETION WITH THE AID OF THE ISOLATED PERFUSED RAT LIVER. I. INHIBITORY ACTION OF SPORIDESMIN AND ICTEROGENIN. *(E.)* Bullock, G.; Eakins, M. N.; Sawyer, B. C.; Slater, T. F. (C.I.B.A. Lab., Horsham, England). *Proc. R. Soc. Lond. (Biol.)* 186(1085):333-356, 1974.

An isolated perfused liver technique was developed to study the mechanisms underlying bile secretion and th cholestatic actions of icterogenin and sporidesmin. The perfusion medium was a Krebs-Ringer bicarbonate buffer containing bovine serum albumin (5 g%), D-glucose (11 mM), amino acids, sodium lactate (1.5 mm), defibrinated blood from the same albino strain as liver donors (25 ml/100 ml), and streptomycin (7.5 mg). The perfused liver produced bile for 3-5 hr at a stea rate slightly above that in intact rats possessing external biliary cannulae. The addition of ethanol (final concentration 27 mM) to control perfusion had no significant effect on bile flow or liver morphology other than a decrease in the numbers of multi- and mono-vesicular bodies and in their relative proportio in the cytoplasms. There was a large, transient increase in perfusate lactate to pyruvate ratio and a sharp fall in the perfusate pH. Sporidesmin (2 mg in ethanol-buffer solution) rapidly decreased bile flow and retarded the increase in the lactate to pyruvate ratio and the decrease in perfusate pH seen in ethano controls. Electron micrographs of livers after sporidesmin administration showed large regions of the bile canaliculi devoid of microvilli and the appearance in the cytoplasms of lysosomal-like structures containing numerous glycogen granules. Icterogenin (4 mg in ethanol-buffer solution) produced a rapid cholestasis and inhibited the changes in lactate to pyruvate ratio and perfusate pH seen in ethanol preparations. Electron micrographs of icterogenin-treated livers revealed changes in the canalicular membrane, extrusion of material into the canalicular lumen, and aggregation of lysosomes in the cytoplasm. These studies suggest that bile flow in the rat is seriously affected by disturbances to the canalicular membrane.

6655 BILE ACID METABOLISM IN MAMMALS: VI. EFFECT OF ETHIONINE UPON BILE ACIDS OF RAT BILE. *(E.)* Yousef, I. M.; Kakis, G.; Fisher, M. M. (Dept. Med., Univ. Toronto, Canada). *Lipids* 9(6): 407-414, 1974.

The bile ducts of 12 male and 12 female Wistar rats were cannulated. After 1 hr of bile collection, 6 rats of each sex were given ethionine (1 mg/g) by feeding tube. The bile acid composition of the bile collected during the subsequent 4 hr was analyzed by combined thin layer and gas chromatography. Ethionine reduced bile flow (3rd and 4th hr) and bile acid concentration (4th hr) in female rats. The amino acid had no effect on bile flow in male rats but did decrease biliary secretion of bile acids (1st and 2nd hr). Cholic acid accounted for the bulk of the reduction in total bile acid secretion in females. The increase in total bile acid secretion in males involved all bile acids. The effects of ethionine on bile acid secretion were delayed in female rats, immediate in the males. The changes in bile acid secretion involved only the taurine conjugates in the female studies compared with both taurine and glycine conjugates in the male. These results demonstrate substantial sex differences in the effect of ethionine on bile acid metabolism in the rat.

6656 THE CONTROL OF BILE ACID POOL SIZE: EFFECT OF JEJUNAL RESECTION AND PHENOBARBITONE ON BILE ACID METABOLISM IN THE RAT. *(E.)* Mok, H. Y. I.; Perry, P. M.; Dowling, R. H. (Guy's Hosp. Med. Sch., London, England). *Gut* 15(4):247-253, 1974.

In patients with cholesterol gallstones, there is a diminished bile acid pool and the bile becomes supersaturated with cholesterol. Medical treatment has been aimed at re-expanding the pool to improve cholesterol solubility in bile but as yet the factors controlling the size of the bile acid pool are unknown. Therefore the role of the liver and intestine in controlling bile acid pool size in female Wistar rats was studied and the effect of experimental expansion of the pool on bile acid metabolism and bile lipid composition examined. Bile acid absorption was increased from ileum made hyperplastic by previous jejunectomy and hepatic bile acid synthesis was increased by phenobarbital treatment (1 mg/ml drinking water). Both jejunal resection and phenobarbital significantly increased the size of the bile acid pool from 32.2 ± 0.94 μM/100 g body weight to 42.4 ± 1.71 and 44.4 ± 2.03 resp. However, the effects of these experimental manipulations on bile acid secretion rate, enterohepatic cycling frequency, and synthesis rates were quite different. Jejunectomy caused a 56% increase in bile acid secretion and more rapid cycling of the bile acid pool but the enhanced absorption did not depress bile acid synthesis. In contrast, phenobarbital markedly increased synthesis from 14.5 ± 1.42 μM/100 g/24 hr to 25.9 ± 3.19, but there was no significant change in bile acid secretion and the choleresis seen after phenobarbital was mainly due to an increase in the bile acid-independent fraction of bile flow. In these experimental studies in the rat, expansion of the bile acid pool did not significantly change bile lipid composition or cholesterol solubility in bile.

6657 THE ENHANCEMENT OF MAXIMAL BILIRUBIN EXCRETION WITH TAUROCHOLATE-INDUCED INCREMENTS IN BILE FORM. *(E.)* Goresky, C. A.; Haddad, H. H.; Kluger, W. S.; Nadeau, B. E.; Bach, G. G. (Montreal Gen. Hosp., Quebec). *Can. J. Physiol. Pharmacol.* 52(3):389-403, 1974.

Of the processes involved in the handling of a bilirubin load, the biliary secretory maximum or Tm for bilirubin has been regarded as rate limiting and as a characteristic of liver function. In the present study, bile flow was varied by use of bile acid infusions to determine whether the Tm is indeed constant or whether it varies with flow. Anesthetized dogs, with bile flow stabilized by cholinergic blockade, were studied during taurocholate infusions. In these animals the ductular component of flow is relatively inhibited and the bile flow rate increases approximately in proportion to the rate of excretion of taurocholate. The maximal biliary excretion rate of bilirubin increased linearly with flow and taurocholate excretion, in a significant fashion, but, in contrast to the relation between taurocholate excretion and flow, a significantly large intercept remained on linear extrapolation toward zero flow. The basis for the large intercept is a great increase in the bilirubin concentration in bile as the flow is decreased. This results in a simultaneous sharp increase in the molar ratio (bilirubin/taurocholate) at very low rates. It is inferred, on the basis of the preceding data, that the capacity for bilirubin transport is linked to the secretion of bile acids into bile. At low rates of supply of bile acids, little of the material will reach the centers of the hepatic lobules and the contribution of bile acids to bile flow at the site will be relatively low. At higher rates of bile acid infusion or supply, increased amounts of the bile acids will reach the centers of the lobules and contribute to increased bile formation in these areas. It appears that this is the mechanism which underlies the change in the transport maximum for bilirubin with change in the rate of bile salt excretion.

6658 CHOLESTEROL ESTERIFICATION BY THE RAT LIVER GOLGI APPARATUS. *(E.)* Assmann, G.; Mahley, R. W.; Davis, B. D.; Holcombe, K. S. (Natl. Inst. Hlth., Bethesda, Md.). *Scand. J. Clin. Lab. Invest.* 33(Suppl. 137):23-28, 1974.

Livers of white Holtzmann rats of both sexes were fractionated into various subcellular components. Electron microscope examination showed numerous Golgi apparatus fragments together with large numbers of associated smooth-surfaced vesicular and saccular sections. The larger secretory vesicles contained particles previously identified as very low density lipoproteins (VLDL). Formation of cholesteryl esters in Golgi apparatus fractions was measured using a sonicated mixture of 2-[1-^{14}C oleoyl]-*sn*-phosphatidyl choline and 7-^{3}H-cholesterol as substrates. The isolated Golgi apparatus had significant fatty acyl coenzyme A-cholesteryl acyltransferase activity with an optimum at pH 5.8. When cholesterol esterification was investigated in other cell fractions with assay conditions optimized for the Golgi apparatus enzyme, the extent of esterification by any of the cell fractions was considerably smaller. The cholesteryl esters synthesized by the Golgi fraction enzyme could be specifically localized in the Golgi-VLDL particles. Whether the cholesteryl esters are core constituents of VLDL particles or merely associated with the particle surface constituents during their process of formation needs to be elucidated. The presence of fatty acyl coenzyme A-cholesteryl acyltransferase activity and its concentration in the hepatocyte Golgi apparatus support the concept that VLDLs are assembled in the peripheral elements of this particular cell fraction. The cholesterol-esterifying enzyme may help to maintain normal concentrations of both cholesterol and cholesteryl ester in the liver. The results emphasize the importance of the Golgi apparatus in the assembly of lipoproteins.

6659 BIOSYNTHESIS OF CHOLESTANOL: CONVERSION OF CHOLESTEROL INTO 4-CHOLESTEN-3-ONE BY RAT LIVER MICROSOMES.

(E.) Bjorkhem, I.; Karlmar, K. E. (Dept. Chem., Karolinska Inst., Stockholm, Sweden). *Biochem. Biophys. Acta* 337(1):129-131, 1974.

Low but significant conversion (0.29%) of cholesterol to 4-cholesten-3-one occurred when 0.14 μg of [1,2-^{3}H$_2$]cholesterol was incubated with the microsomal fraction of rat liver homogenate in the presence of nicotinamide adenine dinucleotide (NAD, 0.5-1.0 mM). No significant conversion occurred with the soluble fraction. In the presence of microsomes and NAD, the rate of conversion of cholesterol to 4-cholesten-3-one was almost linear with time; the extent of conversion under optimal conditions was 3-5 μg/g liver/hr. To rule out the possibility that the 4-cholesten-3-one formed from cholesterol was further metabolized to 5-α-cholestan-3-one and/or 5-α-cholestan-3β-ol, a trace amount of [1,2-^{3}H$_2$]cholesterol and 100 μg 4-cholesten-3-one did not affect the amount of 4-[1,2-^{3}H$_2$]cholesten-3-one obtained. Furthermore, incubation of 4-[4-^{14}C]cholesten-3-one with the NAD-fortified microsomal fraction did not produce significant conversion to products with the chromatographic properties of 5-α-cholestan-3-one or 5-α-cholestan-3β-ol. It is suggested that microsomal conversion of cholesterol to 4-cholesten-3-one is the rate-limiting step in the biosynthesis of cholestanol from cholesterol.

6660 THE INVOLVEMENT OF NICOTINAMIDE IN THE BIOSYNTHESIS OF NAD IN ISOLATED PERFUSED RAT LIVER.

(Ger.) Keller, J.; Liersch, M.; Grunicke, H. (Biochem. Inst., Univ. Freiburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1371-1373, 1972.

To study the biosynthesis of NAD from nicotinamide, isolated rat livers were perfused with a hemoglobin-free medium containing a physiological concentration of nicotinamide (10 μM). Incorporation of nicotinamide into NAD occurred at about 40% of the rate found with a physiological concentration of nicotinic acid (5 μM). By using azaserine to block the nicotinic acid pathway, it was demonstrated that nicotinamide does not first undergo deamidation before it is incorporated into NAD. After injection of physiological concentrations of ^{14}C-nicotinamide, only a small percentage of the radioactivity appeared in the bile, ruling out the possibility that nicotinamide is excreted in the bile and undergoes deamidation in the intestine. After addition of ^{14}C-nicotinamide, no appreciable amounts of nicotinic acid nucleotides were detected, but nicotinic acid mononucleotide and particularly the adenine dinucleotide were found in large quantities when nicotinic acid was used as the precursor. These findings suggest that nicotinamide first reacts to form the nicotinamide mononucleotide which then undergoes an exchange reaction catalyzed by NAD-glycohydrolase. When the livers of fasted rats were perfused with an O$_2$-free medium in the absence of glucose, a significant decrease in the ATP level was accompanied by concommitant inhibition of NAD synthesis, indicating that biosynthesis of NAD from nicotinamide, as well as from nicotinic acid, is ATP-dependent. Under anoxic conditions, liberation of nicotinamide decreased, rather than increased, suggesting that NAD-glycohydrolase activity is not inhibited. Nicotinamide levels decreased to control values after a return to aerobic conditions, showing that the nicotinamide can be reutilized.

6661 HIGH BILIARY AND SYSTEMIC EXCRETION OF A GLUCURONIDE DURING ITS HEPATIC SYNTHESIS.

(E.) Gessner, T.; Hamada, N. (Cancer Drug Ctr., Roswell Park Mem. Inst., Buffalo, N.Y.). *Life Sci.* 15(1):83-94, 1974.

Two phases of biliary excretion of *p*-nitrophenyl-glucuronide were observed in isolated Sprague-Dawley rat livers perfused with ^{14}C-*p*-nitrophenol (5-20 μC). Excretion was fast when the rate of synthesis of the glucuronide was maximal, and this maximal rate was maintained by keeping substrate concentrations above 0.1 mM. Glucuronide excretion into bile was slower when the substrate concentration in the perfusate dropped below saturating levels (below 0.1 mM), even though the glucuronide concentration in the perfusate continued to rise during the synthetic period. The rate of biliary excretion remained slow and constant during the postsynthetic period after all detectable substrate had disappeared from the perfusate. Isotopic dilution experiments confirmed that newly synthesized glucuronide forms a hepatic pool of metabolite easily available for biliary excretion, but not readily diluted by the glucuronide in the circulation.

6662 RAT LIVER 3-HYDROXY-3-METHYLGLUTARYL COENZYME A REDUCTASE: A COMPARISON AND IMMUNOLOGICAL STUDY OF PURIFIED SOLUBILIZED PREPARATIONS, AND ALTERATIONS OF ENZYME LEVELS BY CHOLESTYRAMINE FEEDING. *(E.)* Higgins, M. J. P.; Brady, D.; Rudney, H. (Coll. Med., Univ. Cincinnati, Ohio). *Arch. Biochem. Biophys.* 163(1):271-282, 1974.

3-Hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase from Sprague-Dawley rat liver was solubilized with deoxycholate or 2 M salt. The deoxycholate-solubilized preparation was purified through hydroxylapatite chromatography and gel chromatography to the degree that only a single component was detected by polyacrylamide gel electrophoresis. The second preparation was purified to a high level by 2 passages through an agarose column: only 1 minor band was detectable above the main band. The deoxycholate-solubilized HMG-CoA reductase had a molecular weight of 197,000-202,000. Electrophoresis of both preparations treated with mercaptoethanol on polyacrylamide gels in the presence of sodium dodecyl sulfate revealed 1 band with a molecular weight of 65,000. The data are consistent with the trimeric structure consisting of 3 polypeptide chains of apparently identical molecular weight. HMG-CoA reductase solubilized by salt, freeze-thawing, or deoxycholate was tested for cross reactivity with an antibody prepared from the deoxycholate-solubilized preparation. Despite differences in specific activity, stability to cold, and salt requirement for preservation, the 3 preparations were immunologically indistinguishable. Administration of cholestyramine (2% of diet) to rats greatly stimulated the synthesis of enzyme protein without affecting decay rates. Comparison of ratios of enzymic activity to the amount of antigen-antibody precipitate showed that the enzyme from cholestyramine-treated animals ad a higher specific activity than that from untreatd rats. There were no immunologic differences beween the enzymes from both groups. The data indiate that changes in the state of the enzyme protein, s well as changes in the rate of protein synthesis, re important factors in the regulation of HGM-CoA eductase. Studies based only on enzyme specific acivity may fail to reveal significant changes in enyme protein concentrations.

663 INDUCTION OF ALKALINE PHOSPHATASE ACTIVITY BY DIBUTYRYL ADENOSINE 3':5'-CYCLIC MONOHOSPHATE IN ANEUPLOID RAT LIVER CELLS. *(E.)* Nose, .; Katsuta, H. (Inst. Med. Sci., Univ. Tokyo, Japan). *Exp. Cell Res.* 87(1):8-14, 1974.

lkaline phosphatase-I activity in cultured JTC-25-5 rat liver cells increased 10-fold when the cells ere incubated in the presence of dibutyryl cyclic MP (0.25 mM) and theophylline (1.0 mM). Alkaline hosphatase-II activity did not change significantly nder the same conditions, indicating that the 2 acivities are regulated by different mechanisms. Aong 6 subclones of this strain, alkaline phosphatase- activity was inducible in 4 with dibutyryl cyclic MP and theophylline. Extensive cytoplasmic elongaion was observed in inducible and uninducible sublones, and both types incorporated ^{3}H-dibutyryl cylic AMP to the same degree. Induction of alkaline phosphatase-I was inhibited by cycloheximide (1 μg/ml) but not by cytosine arabinoside (10^{-5} M) or colchine (10^{-7} M). More then 90% of alkaline phosphatase-I activity was recovered from the particulate subcellular fractions. Inhibition of alkaline phosphatase-I by cycloheximide suggests that *de novo* synthesis of protein is necessary for the induction.

6664 ENERGY REQUIREMENT FOR THE TRANSPORT OF REDUCING EQUIVALENTS FROM CYTOSOL TO MITOCHONDRIAE IN PERFUSED RAT LIVER. *(E.)* Krarup, N.; Olsen, C. (Inst. Physiol.; Univ. Aarhus, Denmark). *Life Sci.* 15(1):65-72, 1974.

The system transporting reducing equivalents across the mitochondrial membrane was investigated in perfused Wistar rat liver by following the flux of reducing equivalents from cytosol to mitochondria, estimated by ethanol elimination, and the redox potentials on both sides of the mitochondrial membrane, estimated from the lactate/pyruvate and β-hydroxybutyrate/acetoacetate ratios in the effluent medium. The power of the transport system was calculated to be 1.8×10^{-3} cal/min/g liver wet weight, which was about 1% of the metabolic rate. Uncoupling by 2,4 dinitrophenol increased the oxygen consumption 30%, but the ethanol elimination decreased despite a fall in the redox potential gradient. This resulted in a 50% decrease in power of the transport system. The data indicate that the transport of reducing equivalents from cytosol to mitochondria is energy dependent.

6665 LIPID METABOLISM IN SUCKLING RATS WITH FATTY LIVER INDUCED BY HYPOXIA. *(E.)* Chiodi, H.; Whitmore, S. (Dept. Ergonomics, Univ. California, Santa Barbara). *Experientia* 30(5):463-465, 1974.

Chronic hypoxia due to a simulated altitude of 4600 m induced hyperlipemia and fatty liver in suckling Sprague-Dawley rats maintained under hypoxic stress for 10-11 days, beginning at the age of 1 day. Total lipids in plasma and liver in chronically hypoxic animals were significantly greater than in 12-day-old controls. In the hypoxic rats, blood β-hydroxybutyrate and acetoacetate values were not significantly different from those of the controls. The β-hydroxybutyrate:acetoacetate ratio decreased by 21% in hypoxic animals. When rats were returned to sea level pressure for 8, 24, or 48 hr prior to sacrifice, the levels of total lipids in plasma and liver decreased significantly. In animals kept at sea level pressure for 24 hr, total liver lipids fell to normal values and β-hydroxybutyrate values increased significantly over those of rats sacrificed immediately after removal from the hypobaric chamber. The 3 animals which survived 48 hr outside the chamber had higher liver lipid levels and low β-hydroxybutyrate values compared with hypoxic rats kept 24 hr at sea level pressure before sacrifice. Apparently liver functions in the 3 rats were impaired to such a degree that recovery under the influence of normal oxygen pressure was no longer possible. The decrease in the β-hydroxybutyrate:acetoacetate ratio in hypoxic rats may have been due to low levels of hepatic glycogen in these animals. The increase in β-hydroxybutyrate blood levels in hypoxic rats returned to sea level for several hr prior to sacrifice could be due to the sudden removal of the depressant effect of hypoxia on lipid oxidation.

6666 STIMULATION OF HEPATIC DRUG-METABOLIZING ENZYMES BY DDT, POLYCYCLIC HYDROCARBONS OR PHENOBARBITAL IN ADRENALECTOMIZED OR CASTRATED MICE.

(E.) Chhabra, R. S.; Fouts, J. R. (Natl. Inst. Hlth., Res. Triangle Park, N.C.). *Toxicol. Appl. Pharmacol.* 28(3):465-476, 1974.

In rats benzpyrene treatment increases the hepatic microsomal aniline hydroxylase pH optimum from 7 to 8. No such shift was observed in male Swiss-Webster mice treated with benzpyrene (50 or 200 mg/kg/day i.p.) for 3 days. Further studies on hormonal regulation of ethylmorphine-*N*-demethylase, aniline, and benzpyrene hydroxylase in mice indicated that adrenalectomy, castration, or both together did not lower the basal activities of these enzymes in mice. In rats with similar operations, basal activities were reduced 50-90% depending on the enzyme. In mice without adrenals and/or testes, i.p. administration of DDT (200 mg/kg), benzpyrene (200 mg/kg), 3-methylcholanthrene (50 mg/kg), or phenobarbital (100 mg/kg) stimulated the drug-metabolizing enzymes to a somewhat higher extent than that observed in sham-operated controls. This contrasts with the effects of inducers on sham-operated *versus* adrenalectomized and/or castrated rats. These findings suggest that rats and mice differ in hormonal regulations of basal activities of hepatic microsomal-drug metabolizing enzymes and in the response of these enzymes to pretreatment of animals with inducers.

6667 THE ROLE OF METABOLISM IN CHLOROFORM HEPATOTOXICITY.

(E.) Lavigne, J. G.; Marchand, C. (Fac. Med., Univ. Montreal, Canada). *Toxicol. Appl. Pharmacol.* 29:312-326, 1974.

Pretreatment of male Sprague-Dawley rats with phenobarbital (50 mg/kg/day for 3 days, i.p.), 3-methylcholanthrene (40 mg/kg/day for 2 days, i.p.), or 3,4-benzpyrene (20 mg/kg/day for 2 days, i.p.) increased the toxicity of chloroform (0.5 ml/kg i.p.), as reflected by increased SGPT and a decrease in liver glucose-6-phosphatase activity. This enhancement of the toxicity of $CHCl_3$ was associated with an increase in $CHCl_3$ metabolism, as measured by pulmonary excretion of $^{14}CO_2$. An inhibitor of drug metabolizing enzymes, 2 diethylaminoethyl-2,2-diphenylvalerate hydrochloride (40 mg/kg i.p.), decreased pulmonary $^{14}CO_2$ excretion. Although these observations were compatible with the hypothesis that $CHCl_3$ acts through a metabolite, no metabolite could be detected by gas-liquid chromatography of blood or liver. In addition, there was no quantitative correlation between the increase in toxicity and the increase in $CHCl_3$ metabolism. Finally, 2 diethylaminoethyl-2,2-diphenylvalerate hydrochloride did not decrease $CHCl_3$ metabolism or result in a decrease in $CHCl_3$ liver concentration. Pretreatment with the inhibitor was associated with a significant increase in $CHCl_3$ concentration in all tissues except lungs and muscle 4 hr after injection of the halogenated hydrocarbon.

6668 THE INFLUENCE OF AGE, PHENOBARBITAL AND CARBONTETRACHLORIDE ON THE BROMSULPHTHALEINE BINDING TO CYTOSOL OF VARIOUS ORGANS AND ON THE BROMSULPHTHALEINE ELIMINATION FROM THE BLOOD.

(E.) Muller, D.; Klinger, W. (Inst. Pharmacol. Toxicol., Friedrich Schiller Univ., Jena, Germany). *Acta Biol. Med. Ger.* 32(2/3):211-218, 1974.

BSP (50 mg/kg) was administered i.p. to Wistar rats aged 3, 5, and 20 days and i.v. to rats aged 60 and 120 days. The *in vitro* binding of BSP to liver cytosol was very low in 3-day-old rats and increased continuously with increasing age. Phenobarbital (60 mg/kg i.p.) given for 3 days enhanced BSP binding to liver cytosol only in 20-day-old rats; no effect was observed on younger rats given phenobarbital directly or indirectly through their mothers' milk. Pretreatment for 6 days was required to enhance binding in older rats. A single injection of CCl_4 (1 ml/kg) diminished the BSP binding to liver cytosol of 20-day-old rats but had no effect on the other age groups. BSP binding to kidney, muscle, and brain cytosol was lower than the binding to liver cytosol and was not clearly influenced by age or phenobarbital treatment No BSP was detectable in muscle and brain cytosol after *in vivo* administration. BSP elimination from blood was more rapid in adult than in young animals; phenobarbital accelerated the elimination only in 20-day-old rats. The BSP concentrations in liver and kidney cytosol after *in vivo* administration appeared to reflect the changes in BSP serum level. It is suggested that BSP-binding proteins are not importan for the distribution volume of BSP or other organic anions.

6669 THE EFFECTS OF AZATHIOPRINE ON CCl_4 INDUCE CIRRHOSIS IN THE RAT.

(E.) Ranek, L.; Bremmelgaard, A.; Dupont, B.; Jorgensen, M.; Keiding S.; Thomsen, P.; Tyrsted, G. (Rigshosp., Copenhagen, Denmark). *Beitr. Pathol.* 152(1):66-73, 1974.

Azathioprine (6 mg/kg/day) was given p.o. for 6 mont to female Wistar rats. Half the rats also received CCl_4 (0.1 ml/100 g) injections twice weekly (i.m. du ing the first 3 months and s.c. during the last 3). Rats receiving CCl_4 alone or no treatment served as controls. Azathioprine augmented the CCl_4-induced mortality, with only 8 of 21 rats alive after 6 mont compared with 15 of 20 rats given CCl_4 alone. No deaths occurred in rats receiving azathioprine alone Liver histology was the same in rats receiving CCl_4 with and without azathioprine. Cirrhosis was presen in 5 survivors in the azathioprine-CCl_4 group and in 9 survivors in the CCl_4 group. Necroses tended to b more prominent in the former group, but inflammatory reactions were equally pronounced in both groups. I rats given azathioprine and CCl_4, liver weight, DNA content, and RNA synthesis were significantly increased, indicating an enhanced liver regeneration i surviving animals. Simultaneously, the hydroxyproli content was reduced, suggesting inhibition of fibroenesis. Azathioprine alone decreased liver RNA con- ent despite an increased synthesis rate, as measured incorporation of ^{32}P-orthophosphate into RNA. The ecreased fibrogenesis and enhanced regenerative ac- ivity in livers of surviving azathioprine-treated nimals provide some support for the clinical use of zathioprine in chronic active liver disease in man.

70 PREVENTION OF HALOTHANE INDUCED CHANGES IN RAT LIVER ENZYMES BY 3-AMINO-1,2,4-TRIAZOLE.

.) Langhans, W.; Schimassek, H. (Inst. Biochem. , Univ. Heidelberg, Germany). *Biochem. Pharmacol.* 3(2):403-409, 1974.

retreatment of male Wistar rats with 3-amino-1,2,4- riazole (85 mg/100 g i.p.) inhibited the increase n liver glycerol-3-phosphate oxidase activity induced halothane treatment (exposure to 1 vol% of a halo- hane-O_2 mixture for 1 hr daily for 14-17 days). The ame inhibitory effect of aminotriazole was found in drenalectomized rats, even though enzyme activity as increased 290% by halothane alone or by 560% com- ared with nonadrenalectomized control rats. The ffect of the halothane metabolite trifluoracetate 30 µM/100 g at normal water consumption for -17 days) on glycerol-3-phosphate oxidase was not ounteracted by aminotriazole. Trifluoroacetate in ombination with aminotriazole increased the enzyme ctivity by 280% in intact rats and by 340% in adre- alectomized rats. Aminotriazole also prevented the ncrease in the activity of malic enzyme, nicotanimide denine dinucleotide phosphate (NADPH)-oxidase, and DH produced by halothane treatment. The induction of lycerol-3-phosphate oxidase could not be counteracted actinomycin D because actinomycin itself increased he activity of this enzyme by 70%.

71 LIVER INJURY FOLLOWING HALOTHANE ANESTHESIA IN PHENOBARBITAL-PRETREATED RATS. *(E.)*

eynolds, E. S.; Moslen, M. T. (Peter Bent Brigham osp., Boston, Mass.). *Biochem. Pharmacol.* 23(2): 89-195, 1974.

inear foci of centrolobular necrosis on the posterior spect of the liver were consistently produced by 5 r of anesthesia with 0.85% halothane in young male harles River rats pretreated with phenobarbital (1 /liter drinking water) for 30 days. Microsomes solated from livers of these animals immediately fter completion of anesthesia had elevated lipid- onjugated diene contents, decreased cytochrome P- 50 contents, and decreased ^{14}C-glycine incorpora- ion into protein *in vivo*. The lipid-conjugated iene contents and ^{14}C-glycine incorporation, but ot the cytochrome P-450 contents, returned to pre- nesthesia levels within 2 hr. None of these altera- ions was evident in livers of saline-pretreated rats .23 g NaCl/liter drinking water) after halothane nesthesia. Apart from the persistence of decreased ytochrome P-450 levels in phenobarbital-pretreated nimals, alterations in lipid-conjugated diene and lycine incorporation did not occur after repeated nesthesia at 48-hr intervals, nor was hepatic ne- rosis as evident. However, anesthesia recovery imes increased significantly. These results indicate that halothane metabolites are directly hepatotoxic and that repeated anesthesia with halothane at 2-day intervals decreases its hepatotoxic effect, presumably by interfering with its metabolism to toxic metabolites by the endoplasmic reticulum. Similar morphologic lesions were produced in phenobarbital-pretreated animals by feeding minute doses of carbon tetrachloride as low as (4 mg/kg i.p.).

6672 SPECIES DIFFERENCES IN HEPATIC GLUTATHIONE DEPLETION, COVALENT BINDING AND HEPATIC NECROSIS AFTER ACETAMINOPHEN.

(E.) Davis, D. C.; Potter, W. Z.; Jollow, D. J.; Mitchell, J. R. (Natl. Heart Lung Inst., Bethesda, Md.). *Life Sci.* 14(11): 2099-2109, 1974.

Acetaminophen-induced hepatic necrosis was studied in Golden Syrian hamsters, General Purpose mice, Sprague-Dawley rats, guinea pigs, and rabbits given the analgesic (150-1500 mg/kg i.p.) 48 hr previously. Hamsters were susceptible to a single dose of 150 mg/kg with centrilobular necrosis appearing in 64% of animals. After administration of 400 mg/kg acetaminophen, necrosis was present in 100% of surviving hamsters (20% mortality) and the severity of necrosis was increased. A dose of 375 mg/kg acetaminophen induced hepatic necrosis in 46% of surviving mice (3%) mortality. As in hamsters, the incidence and severity of necrosis increased with higher doses (e.g., 99% showed necrosis after 750 mg/kg). Rats, guinea pigs, and rabbits were relatively resistant to hepatic injury even when the dose of acetaminophen was at or above the LD_{50} dose. Species susceptibility to hepatic injury was directly correlated with the extent of covalent binding of the presumed toxic metabolite of acetaminophen to hepatic microsomes. Binding was greater in hamsters and mice and markedly less in rabbits, guinea pigs, and rats. There was also a direct correlation between the severity of necrosis and the rate of hepatic glutathione depletion after acetaminophen. At 300 mg/kg, acetaminophen depleted hepatic glutathione 80% in hamsters and mice, but only 30% in guinea pigs and 10% in rats. The results support the hypothesis that the electrophilic arylating agent formed from acetaminophen *in vivo* is preferentially detoxified by conjugation with glutathione and that arylation of hepatic macromolecules occurs only when glutathione availability is exceeded. While the identity of the arylating metabolite is uncertain, an N-hydroxy derivative seems the most likely candidate.

6673 THE EFFECT OF ETHANOL ALONE AND COMBINED WITH DRUGS ON MICROSOMAL ENZYME ACTIVITY IN RAT LIVER.

(Ger.) Bode, C.; Bode, J. C.; Martini, G. (Med. Clin., Univ. Marburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:909-910, 1973.

Five groups of 8-10 male Wistar rats each received a standard diet (20% protein) *ad libitum* plus (1) water; (2) a 15% ethanol solution (w/v) *ad libitum;* (3) 15% ethanol *ad libitum* + 5 g/kg/day ethanol p.o. through an esophageal tube; (4) water + 100 mg/kg/day phenobarbital; (5) water, 100 mg/kg/day phenobarbital, and 15% ethanol *ad libitum* + 5 g/kg/day p.o. Rats fed a low-protein (5%) diet received either water *ad libitum* (group 6) or 15% ethanol *ad libitum* + 5 g/kg/day p.o. (group 7). In groups (2) and (3) the activities of acetanilide hydroxylase and NADPH- and NADH-dependent cytochrome c reductase in the liver were decreased to 50% of control values, while the activities of 4ene-5-steroid reductase and glucose-6-phosphatase were increased by 150-200%. In group (4) no changes occurred in acetanilide hydroxylase or NADH-dependent cytochrome c reductase activities, while those of NADPH-dependent cytochrome c reductase, steroid reductase, and glucose-6-phosphatase increased significantly. In group (5) only glucose-6-phosphatase activity increased significantly; no changes occurred in the activities of the other enzymes. In group (6) the activities of acetanilide hydroxylase and NADPH- and NADH-dependent cytochrome c reductase decreased to about 20-30% of their initial values. Simultaneous administration of ethanol to protein-deficient rats (group 7) did not inhibit the activities of these enzymes further. Protein deficiency also reduced steroid reductase activity, while simultaneous administration of ethanol increased it significantly. Glucose-6-phosphatase activity was twice the control values in protein-deficient animals, but administration of alcohol had no effect on its activity. These findings indicate that ethanol has different effects on the various microsomal enzymes. Discrepancies found in drug metabolism in alcoholics may be attributed to ingestion of low-protein diets and sedatives and other drugs.

6674 EFFECT OF ACUTE AND CHRONIC ETHANOL TREATMENT ON HEPATIC TRIGLYCERIDE RELEASE FROM THE RAT PERFUSED LIVER.

(E.) Morland, J.; Oye, I. (Dept. Pharmacol., Univ. Oslo, Norway). *Eur. J. Pharmacol.* 27(2):238-244, 1974.

Male Wistar rats were fed ethanol (30% of total calorie intake) for 5 weeks (chronic ethanol treatment) or iscocaloric sucrose in place of ethanol (controls). Livers from both ethanol-treated and control rats were perfused with 0.18-0.25% ethanol (acute treatment) or without ethanol. Neither chronic nor acute ethanol treatment changed hepatic lipid levels. Chronic ethanol treatment resulted in a significant reduction in hepatic triglyceride and pre-β-lipoprotein release, while acute treatment increased the release of triglycerides and lipoproteins in ethanol-pretreated animals. Liver tryptophan oxygenase activity was significantly reduced by chronic ethanol treatment but not by acute treatment. Although liver protein content was reduced after ethanol perfusion, the decrease was less than reported for the perfused rabbit liver. No chronic or acute effect of ethanol was noted on bile production, BSP excretion in bile, or BSP disappearance from perfusate. The chronic effect of ethanol on triglyceride and lipoprotein release may be related to reduced protein synthesis in liver. The acute effect may be secondary to the established effect of ethanol on triglyceride synthesis or a direct effect on hepatic triglyceride release.

6675 HEPATIC MICROSOMAL ETHANOL-OXIDIZING SYSTEMS: SOLUBILIZATION, ISOLATION, AND CHARACTERIZATION.

(E.) Teschke, R.; Hasumura, Y.; Lieber, C. S. (VA Hosp., Bronx, N.Y.). *Arch. Biochem. Biophys.* 163(1):404-415, 1974.

The solubilization and subsequent separation of the hepatic microsomal ethanol-oxidizing system from alcohol dehydrogenase and catalase activities by DEAE-cellulose column chromatography is described. Absence of alcohol dehydrogenase in the column eluates exhibiting microsomal ethanol-oxidizing system activity was demonstrated by the failure of nicotinamide adenine dinucleotide to promote ethanol oxidation at pH 9.6. Differentiation of the microsomal ethanol-oxidizing system from alcohol dehydrogenase was further shown by the apparent K_m for ethanol (7.2 mM), insensitivity of the microsomal ethanol-oxidizing system to the alcohol dehydrogenase inhibitor pyrazole (0.1 mM), and by the failure of added alcohol dehydrogenase to increase the ethanol oxidation. Absence of catalatic activity in these fractions was demonstrated by spectrophotometric and polarographic assay. Differentiation of the microsomal ethanol-oxidizing system from the peroxidatic activity of the catalase was shown by the apparent K_m for oxygen (8.3 μM), insensitivity of the microsomal ethanol-oxidizing system to the catalase inhibitors azide and cyanide, and by the lack of a H_2O_2-generating system (glucose-glucose oxidase) to sustain ethanol oxidation in the eluates. The oxidation of ethanol to acetaldehyde by the alcohol dehydrogenase- and catalase-free fractions required reduced nicotinamide adenine dinucleotide phosphate (NADPH) and oxygen and was inhibited by CO. The column eluates showing microsomal ethanol-oxidizing system activity contained cytochrome *P*-450, NADPH-cytochrome *c* reductase, and phospholipids and also metabolized aminopyrine, benzphetamine, and aniline.

6676 AN EXPERIMENTAL MODEL FOR THE STUDY OF HEPATIC ENCEPHALOPATHY.

(E.) Norenberg, M. D.; Lapham, L. W.; Nichols, F. A.; May, A. G. (Univ. Rochester Med. Ctr., N.Y.). *Arch. Neurol.* 31(2):106-109, 1974.

A subacute experimental model of hepatic encephalopathy was created in 4- to 6-month-old Sprague-Dawley rats by constructing a portacaval shunt with subsequent feeding of a cationic ammonium exchange resin. The clinical course was characterized by fluctuating levels of consciousness, bizarre behavior, and motor symptoms leading to coma and death. Metabolic acidosis and dehydration were invariably present in the terminal stage. Serum ammonia levels, measured in 7 animals, were greatly elevated (mean, 1169.3 μg/deciliter). Serum glucose levels ranged from 155-364 mg/deciliter and pH values from 7.0 to 7.4. Sodium, potassium, and bilirubin levels remained normal. Histologic abnormalities included proliferation of Alz-

eimer type II astrocytes throughout all layers and
egions of the cerebral cortex. Calculations of as-
rocyte counts and nuclear volumes showed a signifi-
ant degree of hyperplasia and nuclear enlargement.
is model establishes the important role of ammonia
the production of encephalopathy and the associated
oduction of Alzheimer type II astrocytes.

77 THE ASTROCYTE RESPONSE IN EXPERIMENTAL POR-
TAL-SYSTEMIC ENCEPHALOPATHY: AN ELECTRON
CROSCOPIC STUDY. *(E.)* Norenberg, M. D.; Lapham,
W. (VA Hosp., Denver, Colo.). *J. Neuropathol.*
p. Neurol. 33(3):422-435, 1974.

patic encephalopathy was produced in Sprague-Dawley
ts by constructing a portacaval shunt followed by
vage feeding of an ammoniated cation exchange resin.
rum ammonia levels increased from a normal value of
0-285 μg/deciliter to 548-2154 μg/deciliter. Strik-
g behavioral changes occurred, leading to coma and
ath. The principal morphological alteration by
ght microscopy was hyperplasia of Alzheimer type II
trocytes in the cerebral cortex. The concomitant
trastructural change was increased numbers of cyto-
asmic organelles in the astrocytes, particularly in
tochondria and rough endoplasmic reticulum. Some
trocytes showed degenerative changes consisting of
attered cytoplasmic vacuoles, contracted mitochon-
ia, and a greater degree of electron-lucency of the
toplasm than is seen in brains of control animals.
is hypothesized that the proliferative and hyper-
ophic aspects of Alzheimer II astrocytosis reflect
heightened metabolic state associated with ammonia
toxification by the astrocytes. Critical metabolic
bstances are depleted during this abnormal state,
timately leading to the degenerative changes in as-
ocytes. Neuronal dysfunction in hepatic encephalo-
thy may be a direct effect of the increased serum
monia level or a result of the gliopathy induced by
e protracted elevated ammonia levels.

78 EFFECTS OF HAEMOPERFUSION THROUGH CHARCOAL
OR XAD-2 RESIN ON AN ANIMAL MODEL OF FULMI-
NT LIVER FAILURE. *(E.)* Weston, M. J.; Gazzard,
G.; Buxton, B. H.; Winch, J.; Machado, A. L.;
ax, H.; Williams, R. (King's Coll. Hosp. Med. Sch.,
ndon, England). *Gut* 15(6):482-486, 1974.

lminant liver failure was induced in 16 dogs by he-
tic artery ligation following a side-to-side anas-
omosis between the superior mesenteric vein and in-
rior vena cava. Hemoperfusion with activated char-
al was carried out for 10 hr in 5 animals, while 5
imals had a 6-hr hemoperfusion with XAD-2 resin.
e charcoal-hemoperfused animals had a significantly
nger mean survival time (17 hr) than did the 6 non-
rfused controls (9 1/2 hr). The resin-hemoperfused
imals also survived longer but the difference from
ntrols was not statistically significant. Charcoal
moperfusion prevented the progressive rise in blood
monia levels observed in controls and resin-hemo-
rfused animals. Resin hemoperfusion was associated
th a rapid fall in serum bilirubin, whereas there
s a progressive rise in serum bilirubin in charcoal-
moperfused and control rats. In the 2 resin-hemoperfused animals given ^{14}C-sodium glycocholate, sequential blood measurements showed its complete removal during a single passage across the perfusion column. Necropsy revealed extensive intraperitoneal hemorrhage due to thrombocytopenia in 4 of the 5 resin-hemoperfused animals. Platelet losses were much less severe during charcoal perfusion.

6679 INCREASED SERUM IMMUNOGLOBULIN LEVELS FOLLOWING PORTACAVAL SHUNT IN THE NORMAL RAT. *(E.)* Keraan, M.; Meyers, O. L.; Engelbrecht, G. H. C.; Hickman, R.; Saunders, S. J.; Terblanche, J. (Med. Sch., Cape Town, South Africa). *Gut* 15(6):468-472, 1974.

Serum protein changes, weight loss, and survival were compared in rats with an end-to-side portacaval shunt, normal rats, and sham-operated rats. Serum albumin and serum gamma globulin levels in the normal and sham-operated rats showed minimal variation over the 12-week study period. In the shunted rats, there was a progressive fall in serum albumin (from 4.7 to 3.9 g/100 ml) and a progressive increase in serum gamma globulin to a mean final value 4 times higher than the initial level. The serum albumin levels in shunted rats treated with neomycin (25 mg/day by gavage) did not change significantly and the serum gamma globulin levels had returned to preoperative levels by the 12th week. All sham-operated and normal animals survived longer than 20 weeks. Mean survival was 10-14 weeks in large (250-350 g) shunted animals and 29.2 days in small animals (150-250 g). Neomycin doubled the survival time of the small animals but had no effect on survival in large animals. While sham-operated animals gained 30% of preoperative weight, shunted animals lost 20% within 6 weeks and never regained postoperative levels. Neither weekly bleeding (0.5 ml) nor neomycin affected survival of sham-operated animals, but both factors reduced survival of shunted animals. The mean titer of antibacterial lipopolysaccharide antibody remained less than 20 in sham-operated animals, whereas shunted animals had a mean of 640 at the 6th week and a mean of 120 at the 12th week. The observed elevation of gamma globulin and reversals of albumin/globulin ratios in portacaval-shunted animals may represent an immune response to bacterial lipoploysaccharides released into the systemic circulation as a result of the shunt. The hyperglobulinemia of cirrhosis in human subjects may have a similar etiology.

6680 COMPARISON OF END TO SIDE AND SIDE TO SIDE PORTACAVAL SHUNTS IN DOGS AND HUMAN SUBJECTS WITH CIRRHOSIS AND PORTAL HYPERTENSION. *(E.)* Orloff, M. J.; Chandler, J. G.; Charters, III, A. C.; Condon, J. K.; Grambort, D. E.; Modafferi, T. R.; Levin, S. E. (Univ. Hosp., San Diego, Calif.). *Am. J. Surg.* 128(2):195-206, 1974.

End-to-side and side-to-side portacaval shunts were compared in dogs with liver disease, portal hypertension, and ascites and in human subjects with alcoholic cirrhosis. In animal experiments, ammonium tolerance and hepatic blood flow were almost identical in the 2 groups of shunts, whereas liver function and hepatic morphology were slightly but not significantly better after the lateral anastomosis. In 20 human subjects, blood ammonia response to gavage of ammonium citrate and gavage of whole bank blood was similar in patients with end-to-side shunts (10) and side-to-side shunts (10). Long-term studies were performed on 60 selected cirrhotic patients who had elective shunt surgery (25 end-to-side and 35 side-to-side) and on 112 unselected patients who underwent emergency shunt operations (25 end-to-side and 87 side-to-side). There were no significant differences between the 2 types of shunts with regard to incidence and severity of hepatic encephalopathy, long-term survival, and effect on hepatic function after elective or emergency procedures. All of the side-to-side and 96% of the end-to-side shunts remained patent during the 2- to 8-yr observation period. The reduction in splanchnic portal pressure was similar after the 2 types of bypass, and the 2 anastomoses were equally effective in preventing further variceal bleeding. The results indicate that one shunt does not have a clear advantage over the other under conditions other than spontaneous reversal of portal blood flow. To prevent development of fatal ascites, a side-to-side shunt should be mandatory in patients with retrograde flow in the portal vein.

6681 EFFECT OF FREE FATTY ACIDS ON HEPATIC ADENINE NUCLEOTIDE CONTENT AND OXIDATIVE METABOLISM. *(E.)* Mannaerts, G.; Debeer, L. J.; De Schepper, P. J. (Lab. Pharmacol., Catholic Univ., Louvain, Belgium). *Arch. Int. Physiol. Biochim.* 82 (2):357-358, 1974.

'33 DISACCHARIDASE ACTIVITIES IN THE RAT INTESTINE. II. EFFECT OF PROGESTERONE. *.)* Goldstein, R.; Landau, H.; Freier, S. (Shaare dek Hosp., Jerusalem, Israel). *Am. J. Clin. Nutr.* '(8):845-849, 1974.

e effect of progesterone, administered by differ- t routes, on disaccharidase activities in the all intestine was studied in Sabra rats of various es. Lactase and maltase activities in weanling ts were significantly higher 24 hr after s.c. or p. injection of 2-6 mg/100 g progesterone than af- r s.c. or i.p. injection of 2-6 mg/100 g ethyl ol- te. The effect of progesterone on sucrase was ss pronounced. P.o. doses of 4-9 mg/100 g had no gnificant effect on disaccharidase levels. In ckling rats, s.c. administration of 3-10 mg/100 g ogesterone had no effect on sucrase activity and used only a borderline rise in 24- and 48-hr lac- se and maltase activities. Two-month-old rats on at milk diets showed a significant rise in lactase tivity 24 hr after the last of 5 s.c. ethyl oleate jections (3 mg/100 g on alternate days). The ef- ct of progesterone, at the same rate and route, on ctase activity was even greater at 24 and 48 hr. 74 hr, there were no differences between untreated ts on a normal diet and rats treated with proges- erone or ethyl oleate. The s.c. route appeared the fest as mortality was lower without loss of effi- iency. However, 6 mg/100 g progesterone was lethal the majority of weanling rats (5 of 8) whether ministered i.p. or s.c. Suckling rats tolerated mg/100 g s.c. The results show that the effect progesterone on disaccharidase activity is age- ependent and short-lived. Only in adult rats, when ogesterone worked synergistically with goat milk, d the effect last 48 hr. The steroid may have ac- ivated adult cells to produce more enzymes.

734 EFFECT OF 200, 650 AND 1200 R ON THE INTESTINAL DISACCHARASES AND DIPEPTIDASES. *.)* Becciolini, A.; Cariaggi, P.; Arganini, L.; astagnoli, P.; De Giuli, G. (Univ. Florence Med. ch., Italy). *Acta Radiol.* [*Ther.*] *(Stockh.)* 13(2): 41-152, 1974.

emale Sprague-Dawley rats were irradiated in the dominal area with 200 r (21 rats), 650 r (21 rats) 1200 r (39 rats) and sacrificed at 3 hr to 16 days fter irradiation to study postirradiation changes in isaccharase and dipeptidase activities. A 3-phase equence was observed for all doses applied. Enzyme ctivities were higher than controls in the initial hase in all animals killed at 4 and 24 hr after irradiation. This was followed by the intermediate phase at 48 to 72 hr in which enzyme activities as well as total protein content were reduced. In the final phase, appearing after 5 days, all parameters returned to control values. At 1200 r, an initial phase of great enzyme increase occurred. In the intermediary phase there was nearly complete disappearance of maltase and invertin. A residual activity of lactase and leucine aminopeptidase still persisted. There was great variability among animals receiving 1200 r, due to the severity of the gastrointestinal reaction. Moreover, the return to normal values (11-16 days) was not uniform along the length of the intestine. These results indicate that in an animal given a single irradiation to the abdomen, the morphologic alterations in the small intestine are associated with changes in enzyme activities which are both time and dose dependent. The increase in enzyme activities in the initial phase indicates that lesions occur at the level of enzyme synthesis or at the sites where these enzymes are probably stored in an inactive form, waiting to be transferred in the brush border. This could mean the activation of enzymes or the inactivation of inhibitors.

6735 GLYCOPROTEIN SYNTHESIS AND SECRETION BY MUCOSAL BIOPSIES OF RABBIT COLON AND HUMAN RECTUM. *(E.)* MacDermott, R. P.; Donaldson, R. M.; Trier, J. S. (Boston Univ. Sch. Med., Mass.). *J. Clin. Invest.* 54(3):545-554, 1974.

When maintained in organ culture, mucosal biopsies from rabbit colon and human rectum incorporated ^{14}C-leucine into proteins and ^{14}C-glucosamine into glycoproteins at a steady rate for 24 hr. This incorporation probably represents macromolecular synthesis rather than nonspecific attachment of radioactive precursors since incorporation was almost completely prevented by cycloheximide (1 mg/ml). Glucosamine was predominantly incorporated into macromolecules that were ultimately secreted into the incubation medium, while leucine was predominantly incorporated into tissue macromolecules. When studied by autoradiography, cultured rabbit colonic biopsies synthesized and secreted glycoproteins *in vitro* at cellular sites and over a time course observed in previous *in vivo* studies. The interval between exposure of intestinal mucosa to labeled glucosamine and initial secretion of labeled glycoproteins was 3-4 hr. Acetylcholine (10^{-8} to 10^{-6} M) consistently stimulated secretion of labeled glycoproteins but did not alter glycoprotein synthesis. In contrast, cycloheximide had no effect on secretion although it impaired protein synthesis. Rectal biopsies from patients with active ulcerative colitis incorporated increased amounts of ^{14}C-glucosamine into glycoproteins during organ culture and secreted labeled glycoproteins more rapidly than did biopsies from normal subjects. The elution pattern of dialyzed media fractionated by 2B gel filtration suggested an increase in the proportion of high molecular weight glycoproteins in ulcerative colitis biopsies. Presumably, these glycoproteins represented mucus. No new peaks were observed, indicating the composition of rectal mucus is similar in normal subjects and patients with ulcerative colitis.

6736 VASOACTIVE INTESTINAL PEPTIDE STIMULATION OF ADENYLATE CYCLASE AND ACTIVE ELECTROLYTE SECRETION IN INTESTINAL MUCOSA. *(E.)* Schwartz, C. J.; Kimberg, D. V.; Sheerin, H. E.; Field, M.; Said, S. I. (Harvard Med. Sch., Boston, Mass.). *J. Clin. Invest.* 54(3):536-544, 1974.

The effect of vasoactive intestinal peptide (VIP) on cyclic AMP levels, adenylate cyclase activity, and ion transport was tested on *in vitro* preparations of ileal mucosa. At concentrations of 20 μg/ml and 2 μg/ml, resp., VIP caused a 5-fold increase in cyclic AMP in rabbit and human ileal mucosa. In rabbit ileal mucosa, the effect of VIP on cyclic AMP was apparent at 0.1 μg/ml and was maximal at 2.0 μg/ml. Pentagastrin and glucagon (alone or in combination), secretin, carbachol, gastric inhibitory peptide, serotonin, bradykinin, and vasopressin did not increase cyclic AMP levels in rabbit mucosa. Pentagastrin and glucagon also failed to increase the level of the nucleotide in canine ileal mucosa. VIP (100 μg/ml), but not serotonin (6.0×10^{-5} M), stimulated adenylate cyclase activity in a membrane preparation from rabbit ileal mucosa. When added to the serosal side of isolated rabbit ileal mucosa clamped in an Ussing chamber, VIP (2 μg/ml) increased short-circuit current and caused net secretion of both Cl^- and Na^+; net Cl^- excretion exceeded net Na^+ secretion. Addition of VIP (2 μg/ml) to the serosal bathing solution of human ileal mucosa increased short-circuit current to the same extent as that caused by 5 mM theophylline. When added to the luminal bathing solution, VIP did not increase short-circuit current. The effects of VIP on mucosal cyclic AMP metabolism and ion transport are similar to those observed with cholera enterotoxin and certain prostaglandins. Diarrhea in patients with VIP-bearing tumors may be due to interaction between VIP and adenylate cyclase in the small intestine mucosa.

6737 ADENYLATE CYCLASE ACTIVITIES AND ADENOSINE 3':5'-CYCLIC MONOPHOSPHATE CONCENTRATIONS IN VILLUS AND CRYPT CELLS OF RAT SMALL-INTESTINAL EPITHELIUM: RESPONSE TO CHOLERA TOXIN, PROSTAGLANDIN E$_1$ AND HORMONES. *(E.)* De Jonge, H. R.; Hulsmann, W. C. (Dept. Biochem., Erasmus Univ., Rotterdam, Netherlands). *Biochem. Soc. Transact.* 2(3):416-419, 1974.

In order to study long-term effects of cholera toxin and hormones on intestinal cells, adenylate cyclase activities were measured in freshly isolated villus and crypt cells from treated and control rats. Basal and NaF (10mM)-stimulated values did not vary appreciably from duodenum to ileum. Both villus-cell and crypt-cell adenylate cyclase activity increased rapidly in response to prostaglandin E$_1$ (20 μM) and relatively high concentrations of epinephrine (20 μM). The villus-cell:crypt-cell ratio of enzyme activity/mg of protein in the fluoride-stimulated state varied between 0.7 and 0.9, indicating the enzyme activity was almost the same in upper villus and crypt cells. Since only mature villus cells have a well developed brush border, this finding argues strongly against a localization of adenylate cyclase in the brush-border region and agrees with the results of studies performed on rabbit small intestine which indicate that the enzyme occurs preferentially in basal and lateral plasma membranes. Insulin (1-100 ng/ml) and cholera toxin (1-10 μg/ml) did not influence the basal activity of adenylate cyclase to a significant extent during the 15-60 min incubation procedure.

6738 ETHANOL-INDUCED INHIBITION OF HUMAN INTESTINAL ENZYME ACTIVITIES: REVERSAL BY FOLIC ACID. *(E.)* Greene, H. L.; Stifel, F. B.; Herman, R. H.; Herman, Y. F.; Rosensweiz, N. S. (Fitzsimons Army Med. Ctr., Denver, Colo.). *Gastroenterology* 67(3):434-440, 1974.

The effects of ethyl alcohol on intestinal glycolytic enzymes and fructose diphosphatase were studied in 10 normal subjects on a constant synthetic diet containing 100 μg folic acid/day or on an *ad libitum* mixed diet. During the constant diet, ethanol (15 ml 4 times/day for 7 days) caused a 36-45% decrease in the activities of hexokinase, fructose-1-phosphate aldolase, and fructose-1,6-diphosphate aldolase; a 58% decrease in the activity of fructose-1,6-diphosphatase; and a 33% increase in the activity of pyruvate kinase. Folic acid (5 mg 3 times/day) given with ethanol for 7 days prevented the decrease in enzyme activities produced by ethanol alone: there was a small but significant increase in all the enzymes except fructose diphosphatase. Pyruvate kinase activity increased 2.8-fold when both ethanol and folate were given. After 7 days, folic acid alone caused a 1.6- to 2-fold increase in all the enzymes. Mean folate levels in plasma and RBC increased from 1.7 and 116 ng/ml, resp., at the beginning of the study to 34.3 and 196 ng/ml, resp., after folate treatment. Thus, ethanol did not interfere with folic acid absorption or incorporation into RBC. With the *ad libitum* mixed diet, changes in enzyme activities with ethanol and folate were qualitatively similar to those seen during the constant synthetic diet. A dose of glucose with the same number of calories as that provided by the alcohol did not cause the changes seen with ethanol. Therefore, the action of ethanol is not due to its caloric value. If the deleterious effects of ethanol are related to prolonged decreases in various enzyme activities, folic acid may exert a protective action.

6739 THE EFFECT OF CHRONIC UREMIA ON INTESTINAL MITOCHONDRIAL ACTIVITY. *(E.)* Russell, J. E.; Avioli, L. V. (Jewish Hosp., St. Louis, Mo.). *J. Lab. Clin. Med.* 84(3):317-326, 1974.

tochondria were isolated from the duodenal mucosa
female Holtzman rats with experimentally induced
emia of 5 weeks duration, and their ability to
cumulate and release ^{45}Ca and inorganic phosphate
i) was determined. Rats were made uremic by uni-
teral nephrectomy with segmental infarction of
e remaining kidney. When compared to pair-fed
ntrol animals, ^{45}Ca uptake and release were signi-
cantly impaired in the intestinal mitochondria of
emic animals whereas Pi release was unaltered.
ese changes were associated with a decrease in the
spiratory control ratio of intestinal mitochondria
uremic animals and significant decrements in both
ate 3 and State 4 respiration. These data are
nsistent with the hypothesis that chronic uremia
ads to a decrease in electron transport as well as
oxidative phosphorylation of intestinal mito-
ondria.

40 NATURALLY OCCURRING INTESTINAL MALABSORPTION IN THE DOG. *(E.)* Hill, F. W. G.;
lly, D. F. (Med. Sch., Univ. Bristol., England).
. *J. Dig. Dis.* 19(7):649-665, 1974.

study was made of 8 dogs with malabsorption asso-
ated with disease of the small intestine. Clin-
al features included the fact that onset of the
ndrome often followed a systemic illness in which
thargy and signs of acute enteric or gastroenteric
sturbance had occurred. Loss of weight, increased
petite, profuse and often watery and blood-stained
arrhea marked all case histories. Every dog had
w serum cholesterol, 4 had raised plasma GPT le-
ls and 3 had elevated plasma alkaline phosphatase.
eatorrhea was a constant finding, fat assimilation
nging between 73 and 89%. Mucosal disaccharidase
tivity was low, particularly maltase levels. In-
eased excretion in the ^{131}-polyvinylpyrrolidone
st indicated an increased permeability of the in-
stinal mucosa to large molecules and implied that
e hypoproteinemia resulted from protein-losing en-
ropathy. These observations suggest that clinical
labsorption was associated with disease of the
all intestine. Management of the malabsorption in-
lved use of a low-residue glucose and protein diet,
th administration of intestinal astringents, broad-
ectrum antibiotics, and corticosteroids to control
arrhea and suppress inflammatory reaction in the
wel. Response was not good. Morphologic designa-
ons included lymphangiectasea, inflammatory disease
the bowel, neoplastic disease of the bowel, and
llous atrophy. Villous atrophy was sometimes the
le abnormality and sometimes occurred in combina-
on with other intestinal lesions.

41 TWO PATTERNS OF NEUTRAL STEROID CONVERSION IN THE FECES OF NORMAL NORTH AMERICANS.
.*)* Wilkins, T. D.; Hackman, A. S. (Anaerobe Lab.,
rginia Polytechnic Inst. State Univ., Blacksburg).
ncer Res. 34:2250-2254, 1974.

cal neutral steroids from 31 normal male and female
rth Americans eating a normal high meat diet were
alyzed by gas-liquid chromatography. Patterns of
cal neutral steroid conversion fell into two distinct groups. One group (23 subjects) was characterized by extensive conversion of cholesterol and two plant steroids, sitosterol and campesterol, to coprostanol and coprostanone. The second group (8 subjects) showed little or no conversion. Comparison of total mean levels for cholesterol and its conversion products showed no difference between the high and low-conversion groups. These conversion patterns were stable over long periods. If the extent of conversion of neutral steroids is associated with large-bowel carcinogenesis, as has been previously reported, then these two groups may be at different levels of risk.

GENERAL

6755 IN VITRO ADSORPTION OF BILE SALTS TO FOOD RESIDUES, SALICYLAZOSULFAPYRIDINE, AND HEMICELLULOSE. *(E.)* Birkner, H. J.; Kern, F. (Univ. Colorado Med. Ctr., Denver). *Gastroenterology* 67(2):237-244, 1974.

In vitro adsorption of ^{14}C-labeled cholate, chenodeoxycholate, deoxycholate, and taurocholate, as well as ^{3}H-labeled (glycine) glycocholate, to nondigestible food residues, hemicellulose, salicylazosulfapyridine, and cholestyramine was studied. The radioactive bile salts were incubated with food residues and drugs in buffered solutions; following centrifugation, adsorption was estimated from the decrease in radioactivity in the supernatant solution. Certain food residues, especially celery, corn, lettuce, potato, and string beans, adsorbed large amounts of bile salts, especially unconjugated dihydroxy bile salts. A linear relation between the reciprocals of bile salt adsorption and bile salt concentration suggest that adsorption of bile salts to food residues is a uniform and monomolecular process. The amounts adsorbed were 20-60% of that absorbed by cholestyramine which was used as a comparison. Extrapolation to whole foods indicate that modest amounts (173-389 g) of whole kidney bean, potato, string bean, or corn in the diet can adsorb 1 g of chenodeoxycholate at physiological pH and concentration. Bile salt adsorption to food residues was increased at lower pH values and was greater for less polar bile salts, suggesting that the adsorptive process was hydrophobic in nature. Hemicellulose and salicylazosulfapyridine adsorbed only small amounts of bile salts. Bile salt adsorption to food residues might be an important determinant of stool mass and water content in normal man and might also play an important role in fat absorption and bowel function in patients with decreased intestinal bile salt concentration, especially after bacterial deconjugation and dehydroxylation of the bile salts.

6756 SYNTHESIS OF THE VASOACTIVE INTESTINAL PEPTIDE (VIP). *(E.)* Bodanszky, M.; Klausner, Y. S.; Lin, C. Y.; Mutt, V.; Said, S. I. (Dept. Chem. Case Western Reserve Univ., Cleveland, Ohio). *J. Am. Chem. Soc.* 96(15):4973-4978, 1974.

An octacosapeptide with the amino acid sequence proposed for vasoactive intestinal peptide (VIP) was synthesized in solution through isolated intermediates. The protected heptapeptide derivative, *tert*-butyloxy-carbonyl-L-threonyl-L-aspartyl-L-asparaginyl L-tyrosyl-L-threonyl-L-arginyl-L-leucine azide, was coupled to the partially deprotected pentadecapeptide L-arginyl-*N*-benzyloxycarbonyl-L-lysyl-L-glutaminyl-L-methionyl-L-alanyl-L-valyl-*N*-benzyloxycarbonyl-L-lysyl-*N*-benzyloxycarbonyl-L-lysyl-L-tyrosyl-L-leucyl-L-asparaginyl-L-seryl-L-isoleucyl-L-leucyl-L-asparaginamide (hydrochloride). The resulting protected docosapeptide was partially deprotected and acylated with *tert*-butyloxycarbonyl-L-histidyl-L-seryl-L-aspartyl-L-alanyl-L-valyl-L-phenylalanine azide to afford a protected octacosapeptide encompassing the entire sequence of VIP. The protecting groups were removed in a single operation with trifluoroacetic acid. The product was compared with natural (porcine) VIP after purification by countercurrent distribution; the synthetic peptide showed the characteristic biological activities of the natural material in systemic vasodilation and reduction of arterial blood pressure in intact dogs and relaxation of several isolated smooth muscle preparations. Comparisons of the fragments forme in side-by-side degradations of samples of natural and synthetic VIP with specific enzymes support the amino acid sequence proposed for porcine VIP.

6757 EFFECT OF IRRADIATION OF GASTROINTESTINAL DRUG ABSORPTION IN MICE AND RATS. *(E.)*

rwitz, A.; Doull, J. (Univ. Kansas Med. Ctr., Kansas ty). *Radiat. Res.* 59:606-613, 1974.

udies were conducted to determine the effects of blethal doses of x-irradiation on passive gastro- testinal absorption of sulfadiazine, an acidic ug, and of quinine, a basic drug, in adult male iss Webster mice and Sprague-Dawley rats. Whole dy x-irradiation of mice with 600 r decreased gas- ic absorption of both drugs within 2 hr. The ximal effect was seen at 24 hr after irradiation, th inhibition lasting for 5 to 6 days. Similar fects were observed in rats receiving 400 or 800 Irradiated mice receiving sulfadiazine by i.p. jection and irradiated rats receiving the drug by odenal intubation were able to absorb sulfadiazine readily as controls. Rats receiving 600 r to the dy or to the head only absorbed sulfadiazine more adily than rats receiving whole body irradiation, t absorbed the drug less readily than controls. ug levels in rats receiving only head irradiation, ich is known to delay gastric emptying, approached ose in nonirradiated controls after 60 min. Thus, appears that delayed gastric emptying is the most portant factor inhibiting gastrointestinal absorp- on after x-irradiation of rats and mice.

58 QUANTITATIVE MEASUREMENT OF GASTROINTESTINAL BLEEDING IN RATS: THE EFFECT OF NONSTEROIDAL TI-INFLAMMATORY DRUGS. *(E.)* Menassé-Gdynia, R.; rupp, P. (Ciba-Geigy Ltd., Basel, Switzerland). *xicol. Appl. Pharmacol.* 29(3):389-396, 1974.

e effect of various nonsteroidal anti-inflammatory ugs on gastrointestinal bleeding was studied in le inbred Fischer rats using ^{51}Cr-labeled RBC. All ugs inhibited kaolin-induced paw edema at concen- ations tested. Indomethacin (5 mg/kg), acetylsali- lic acid (240 mg/kg), diclofenac sodium (17 mg/kg), enylbutazone (113 mg/kg) and sodium salicylate 90 mg/kg) all led to loss of large amounts of ood into feces within 24 hr. Bleeding generally sted for 3 days following a single dose of the ti-inflammatory agents. Indomethacin was the most rmful agent, causing pronounced bleeding in doses ove 10 mg/kg. With the exception of oxyphenbut- zone, these agents caused a dose-related RBC loss in e feces. While the dose of diclofenac sodium caus- g gastrointestinal bleeding was about 14 times the erapeutic dose, indomethacin and acetylsalicylic cid produced gastrointestinal bleeding at doses close therapeutically active levels. These results emonstrate that the gastric irritant activity of ti-inflammatory agents is not strictly correlated ith their anti-inflammatory activity.

'59 EFFECT OF BIOISOLATION AND THE INTESTINAL FLORA OF MICE UPON EVALUATION OF AN APOLLO IET. *(E.)* Luckey, T. D.; Bengson, M. H.; Kaplan, . (Univ. Missouri Sch. Med., Columbia). *Aerosp. Med.* 5(5):509-518, 1974.

typical Apollo diet, which previously had been ound to be marginal by chemical analysis but adequate or classic mice (weanling CRL-CD-1 Swiss) before and after sterilization, was fed to gnotobiotic mice (weanling CRL-CD-1 Swiss) to determine the effect of different microorganisms on the utilization of a marginal diet. Although the low-iron diet was found to be adequate for classic mice through 3 generations, very few of the gnotobiotic mice reproduced and none reared their young to weaning. The different states of gnotobiotic mice utilized for evaluation of Apollo diet were: germfree and mono- and diassociated mice carrying *Escherichia coli*, *Lactobacillus leichmannii*, *Candida albicans*, *Staphlococcus epidermidis*, and *Bacteroides sp.* The best of the gnotobiotic states for this marginal diet was that in which mice were monoassociated with *S. epidermidis*. For most factors studied, these mice were as good as classic mice; but since they did not reproduce, other problems must have been involved. The mice monoassociated with *E. coli* had a good appearance but very poor survival; presumably, synthesis of enterobactin by *E. coli* depleted the enteric milieu of available iron. Survival was particularly poor in mice which were weak at weaning and which were di-associated with *E. coli* and either *L. leichmannii* or *C. albicans*. The greatest mortality occurred in the 3rd generation of classic mice in bioisolation. Here, a sudden death occurred precipitously and only 20% of the mice survived after 5 weeks. In conditions such as radiation treatment for cancer or treatment with immunosuppressive therapy, humans harboring potentially hazardous microflora are placed in strict bioisolation. The results suggest that these patients should have a positive means for microflora control, including possible oral inoculations with vitamin-synthesizing organisms.

6760 AN INHIBITORY INNERVATION AT THE GASTRODUODENAL JUNCTION. *(E.)* Anuras, S.; Cooke, A. R.; Christensen, J. (Univ. Iowa Med. Coll., Iowa City). *J. Clin. Invest.* 54(3):529-535, 1974.

Transverse muscle strips (2 mm wide) which were cut serially from the gastroduodenal junction in opossums, cats, dogs, and man were subjected to rectangular pulse stimulation of 0.5 millisec pulse duration at frequencies varying from 1-20 Hz to investigate inhibitory innervation at the gastroduodenal junction. The electrical stimulation induced relaxation in strips from the thickened circular muscle proximal to the mucosal junction in all of the opossums and cats, some of the dogs, and 1 human specimen. Weak relaxations also occurred in the first few strips below the mucosal junction in some of the opossums. All other strips contracted or showed no response. The relaxation in opossums was abolished by tetrodotoxin (10^{-7} M) but was not affected by antagonists to adrenergic and cholinergic transmission nor by tripelennamine, methysergide, pentagastrin, secretin, cerulein, or cholecystokinin. The optimal frequency for stimulus-relaxation was 12 Hz. The chronaxy for stimulus-relaxation was 0.85 millisec. Junctional strips displayed greater resistances to stretch than those remote from the gastroduodenal junction. The junctional muscle possessed a nonadrenergic inhibitory innervation which is either absent or not manifested in adjacent muscle of the stomach and duodenum, suggesting the existence of a distinctive inhibitory neural control mechanism for pyloric muscle.

DIAGNOSTIC PROCEDURES

6789 IMPROVEMENT OF PANCREATIC IMAGING. *(E.)* Mattar, A. G.; Laor, Y. (Buffalo Gen. Hosp., N.Y.). *J. Nuclear Med.* 15(8):707-708, 1974.

In a pancreas image study of 8 patients referred for pancreas scanning, i.v. administration of ^{99m}Tc-sulfur colloid was followed 15-30 min later by i.v. injection of ^{75}Se-selenomethionine. Scintillation camera imaging was begun immediately. Multiple positioning of the patients was employed to determine optimum separation of pancreas and liver images: (1) supine; (2) on right side; and (3) on right side with pelvis elevated on a pillow. In all positions, the detector head was adjusted at an anterior oblique angle, tilted 10 degrees cephalad as well as 10 degrees to the right side of the patient. In the shift from supine to right side positions, the spleen moved medially and downward as the liver moved upward and to the right, thus increasing the anatomical separation between the 2 organs and resulting in maximum possible image separation. If it is anticipated that the pancreas image may be masked by that of the liver or if such a situation arises during the scintigraphic examination, the right-sided positions should be used.

6790 ENHANCEMENT OF PANCREATIC CONCENTRATION OF ^{75}SE-SELENOMETHIONINE. *(E.)* Winston, M. A.; Guth, P.; Endow, J. S.; Blahd, W. H. (VA Wadsworth Hosp. Ctr., Los Angeles, Calif.). *J. Nucl. Med.* 15(8):662-666, 1974.

To improve the reliability of pancreas scanning with ^{75}Se-selenomethionine, the effects of various stimulatory agents on tracer uptake (4 µC i.v. or i.p.) were studied in female Wistar rats. Pancreatic tracer concentration was mildly enhanced by bethanechol chloride (1.0 mg/kg i.v.) but was depressed by vasopressin (3.0 U/kg i.p.) and propantheline bromide (3.0 mg/kg i.v.). Glucagon (1.0 mg/kg i.v.) had no effect on tracer accumulation, while pancreozymin-cholecystokinin (4.0-8.0 U/kg i.v.) had little effect although the results were variable. The combination of bethanechol chloride followed by pancreozymin-cholecystokinin increased pancreatic tracer concentration by about 100% compared with control values. The effects of the 5 drugs on the liver and small intestine paralleled pancreas results but with less variation. The combined bethanechol chloride-pancreozymin regimen was evaluated in 15 patients, including 2 with acute pancreatitis, 2 with severe chronic pancreatitis, 1 with a pancreatic pseudocyst, and 10 with no known pancreas disease but with abdominal pain or suspected carcinoma. Bethanechol chloride (5 m.g.) was administered s.c. followed in 15 min by pancreozymin (1 U/kg) instilled i.v. over a 3-4 min period; ^{75}Se-selenomethionine (3 µC/kg) was given 1 min later and imaging begun immediately. The pancreas was readily visualized in all cases except 1 with severe chronic pancreatitis. Visualization was fair to good in the other cases of pancreatitis, excellent in the case of the pseudocyst, and good to excellent in all cases with a normal pancreas. No pancreatic disease was found in the latter group during a 6-month follow-up. Side effects were mild and consisted of slight cramping and nausea during pancreozymin administration. Study of an additional 35 patients yielded no false-positive results despite a high incidence of alcoholism and pancreatic inflammatory conditions. Two cases of pancreatic carcinoma and 1 of severe chronic pancreatitis were discovered due to nonvisualization of all or a portion of the gland. Stimulation of pancreatic tracer uptake by bethanechol chloride and pancreozymin is probably accomplished by a combination of enhanced blood flow and enzyme synthesis.

6791 TECHNIQUE FOR ENDOGASTRIC TITRATION OF GASTRIC JUICE WITH AN INTESTINAL TRANSMITTER. *(Ger.)* Unger, W.; Kaess, H. (Med. Clin., Univ. Heidelberg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:830-832, 1973.

A modification of the technique cf Wolters, et al. was studied *in vitro* and *in vivo* to determine the error involved. The system consisted of 2 tubes fastened to one another. A pump continuously instilled 0.1 N HCl into the stomach through one of these tubes, while the other was used for addition of 1 N KHCO$_3$. An endoradiosonde, consisting of an antimony-zinc electrode and a radio transmitter, was attached to the distal end of the tube system, and the pH was transmitted over an antenna to a receiver attached to an electronically controlled limit value switch which was set to pH 3.5. Bicarbonate was added when the pH fell below this level. The position of the sonde in the stomach was monitored radiologically. A preliminary *in vitro* test demonstrated that errors were less than 5% when HCl was instilled at a rate of 5-20 mEq/30 min. The system was also tested *in vivo* on 10 normal subjects after administration of atropine (1 mg i.v.), 6 patients with histamine-resistant achlorhydria, and 4 patient who had undergone the Billroth II procedure. In all operated patients, more bicarbonate than HCl was used; errors of measurement were less than 25% in 25 test periods and greater than 50% in 10 test periods This is attributed to transpyloric bicarbonate losse Errors of 30% in both directions were found in nonoperated patients with achlorhydria. Influx of bicarbonate from the saliva and duodenal and gastric juice and loss of H$^+$ by transmucosal diffusion and buffering by gastric mucus might account for low values. Acid or bicarbonate could also be lost through the pylorus.

6792 RADIOLOGICAL EXAMINATION OF THE SMALL INTESTINE IN PATIENTS WITH MELANOMA. *(Dut.)* Tuynman, F. H. B.; Lagaaij, M. B. (Acad. Hosp., Leiden, Netherlands). *Ned. Tijdschr. Geneeskd.* 117(38):1412-1415, 1973.

Case reports are presented for 2 men and 1 woman, aged 45-60 yr, who developed multiple metastases in the small intestine from malignant melanomas of the femur, pectoral region, and palate, resp. The period between removal of the primary tumor and detection of metastases in the small intestine was 6.5, 3, and 11 yr, resp. Metastases were detected radiologically in all 3 patients, 2 of whom had no clinic symptoms of intestinal involvement. Nodular or

ypoid filling defects were found in x-rays from
3 patients. Central ulcerations in the metasta-
were visualized as a "target lesion" or "bull's
" or, in 1 case, as a central cleft. An autopsy
this patient showed that all of the many metas-
es in the small intestine had superficial ulcer-
ons. Since hematogenous metastasis of malignant
anomas to the small intestine is relatively com-
, radiological examinations are recommended for
patients when it is important to know about the
sence or absence of metastases. Since it is
ier for the patient to tolerate, simple to per-
m, and gives better results than other techniques,
eroclysis *via* duodenal intubation is recommended
radiological examination of these patients.

3 QUALITATIVE AND QUANTITATIVE BILE ACID ANALYSIS OF URINE AS A DIAGNOSTIC AID IN
DIFFERENTIAL DIAGNOSIS OF JAUNDICE. *(Ger.)*
x, P. (Med. Clin., Univ. Freiburg, Germany).
a. *Dtsch. Ges. Inn. Med.* 79:950-952, 1973.

studies of the sulfate ester fraction of bile
is, differences were found in urinary excretion
3β-hydroxy-5-cholenic acid, which is produced
in the liver, and deoxycholic acid, produced
side the liver, in various forms of cholestasis.
acute hepatitis deoxycholic acid accounted for
of the total bile acids in the urine and 3β-
roxy-5-cholenic acid for about 5%. In 1 patient
intrahepatic cholestasis and greatly decreased
secretion, 3β-hydroxy-5-cholenic acid made up
of total bile acids in the urine, while deoxy-
lic acid was present only in small quantities.
plete obstruction of the extrahepatic biliary
ct was accompanied, in 4 of 5 patients, by ab-
ce of deoxycholic acid in the urine, while 3β-
roxy-5-cholenic acid accounted for as much as 15%
the total bile acids. A compound was also detec-
which had the same retention time as cholesterol,
its identity must be confirmed by mass spectro-
ry. It is proposed that quantitative determina-
ns of urinary deoxycholic acid and 3β-hydroxy-5-
lenic acid be used as an aid in the differential
gnosis of jaundice.

INDIRECT ISOTOPIC LYMPHOGRAPHY OF THE LIVER: ORIGINAL CONTRIBUTION. SYSTEMATIC
Y. *(Fr.)* Van Waes, L.; Beeckman, P.; Dewinter,
Demeulenaere, L. (St. Andre Clin., Tielt, Bel-
). *Med. Chir. Dig.* 2(5):287-293, 1973.

r injection of 250 μC of colloidal ^{198}Au into
capsule of the liver under laparoscopic control,
r scans were obtained on 13 patients with various
r diseases, including 8 with cirrhosis, and on 3
ents with no evidence of liver disease. Media-
al lymph drainage was demonstrated in 14 of these
atients. In the remaining 2 cases, ^{198}Au may
migrated later and been missed because of the
t half-life of this isotope. Since 1 of these
tients had a normal liver biopsy, this finding
ot considered pathological. In some noncirrhotic
ents, portal lymph nodes were demonstrated along
posterior but no anterior mediastinal drainage,
suggesting the presence of anastomoses between the superficial and deep lymphatics. In all but one of the patients with cirrhosis, ^{198}Au migrated through the deep lymphatics toward the porta hepatis and thoracic duct. This is probably due to involvement of superficial lymphatics in the fibrotic process, rather than to the existence of anastomoses. No migration of ^{198}Au occurred in a patient with cirrhosis complicated by right hydrothorax. This finding indicates that hydrothorax does not result from dynamic insufficiency of the mediastinal lymphatics since this would necessitate that the superficial lymphatics remain permeable. In another patient, anterior mediastinal drainage of lymph persisted although a diagnosis of cirrhosis was confirmed by biopsy. This finding may indicate that the patient was in the early stages of cirrhosis, before portal hypertension developed. Injection of colloidal ^{198}Au into the hepatic parenchyma in 2 patients gave liver scans which masked lymph drainage.

GASTROINTESTINAL DISEASES

ESOPHAGUS

6835 ARGYROPHIL CELLS AND MELANOCYTES IN ESOPHAGEAL MUCOSA.

(E.) Tateishi, R.; Taniguchi, H.; Wada, A.; Horai, T.; Taniguchi, K. (Ctr. Adult Dis., Osaka, Japan). *Arch. Pathol.* 98 (2):87-89, 1974.

Esophagi from consecutive autopsies in Japan were examined for the presence of argyrophil cells and melanocytes. Of the 50 esophagi, 14 contained argyrophil cells, and another 4 contained melanocytes. The 14 esophagi containing argyrophil cells were devoid of melanocytes. Argyrophil cells were unevenly and sparsely distributed in the basal parts of the squamous epithelium; they were never observed among the cells lining the ducts and acini of the esophageal glands. The melanocytes were located in the basal layer of the mucosa. Their dentritic processes were long, tortuous, and extending into the intercellular spaces among other squamous epithelial cells. The results suggest that argyrophil cells are functionally different from melanocytes, and that the incidence of both types may vary among different races. In view of the evidence that bronchial argyrophil cells are the origin of pulmonary oat cell carcinoma, it is hypothesized that oat cell carcinomas in the esophagus are derived from the argyrophil cells in that site.

6836 EFFECT OF AN ANTERIOR FUNDOPLICATION ON LOWER ESOPHAGEAL SPHINCTER COMPETENCE.

(E.) Behar, J.; Biancani, P.; Spiro, H. M.; Storer, E. H. (VA Hosp., West Haven, Conn.). *Gastroenterology* 67(2):209-215, 1974.

The effect of an anterior fundoplication on lower esophageal sphincter competence was studied in 10 patients with reflux esophagitis. Twelve medically treated patients served as controls. Prior to treatment, the incidence of esophageal symptoms and abnormal findings were similar in both groups. All but 1 had a sliding hiatus hernia; most had abnormal esophagoscopy (86%) and a positive acid infusion test (100%). Eight patients had a successful fundoplication, as determined by symptomatic response, adequate repair of the hiatus hernia, negative acid infusion test, and esophagoscopy. In these patients, the mean resting lower esophageal sphincter pressure rose from 10.9 to 24.4 mm Hg and gastroesophageal reflux could not be demonstrated with the pH probe. The pressure increases were not accompanied by restoration of lower esophageal sphincter function determined by sphincter response to graded increments of gastric pressure. The sphincter response was equal to or less than that of gastric pressure increments before and 1 yr after surgery. The remaining 2 surgical patients had recurrence of hiatus hernia. Lower esophageal pressures in these patients rose from 8.5 ± 2.5 mm Hg to only 13.0 ± 9.0 mm Hg and gastroesophageal reflux was readily demonstrated. Regardless of the symptomatic and objective response to medical management (30 ml AlMgOH, 3 times/day, plus bland diet, weight reduction, and liquid antacids), mean resting lower esophageal sphincter pressures and gastroesophageal reflux remained unchanged in the 12 controls after 1 yr of continuous medical treatment.

6837 EPIDERMOLYSIS BULLOSA OF THE OESOPHAGUS WITH OESOPHAGEAL WEB FORMATION.

(E.) Marsden, R. A.; Gowar, F. J. S.; MacDonald, A. F.; Main, R. A. (Aberdeen Roy. Infirm., Scotland). *Thorax* 29(3):287-295, 1974.

Four members (3 women and 1 man, aged 16-28 yr) of a family of 8 had epidermolysis bullosa dystrophica of probable recessive inheritance. In these 4 cases the typical blistering of the skin and oral mucosa had been relatively inconspicuous since infancy. Two patients presented with severe dysphagia but in the others the dysphagia remained comparatively mild. Hemorrhage and regurgitation of blood, with varying degrees of severity, occurred in 3. Radiological evidence of narrowing and irregularity of the upper 1/3 of the esophagus was present in all 4 and was severe in 2. Treatment of the patients with esophageal stenosis by esophagoscopy and bouginage resulte in relief from symptoms, but improvement was not always immediate or long lasting. Routine barium swallow studies in 2 and rapid films in 2 showed the pre ence of postcricoid webs. The webs were single tran verse structures of the type seen in the Paterson-Brown Kelly syndrome. Although the webs may have resulted from the blistering and scarring process of epidermolysis bullosa, the presence of a smooth tong in 4 patients and anemia in 2 suggests the coexisten of the Paterson-Brown Kelly syndrome.

6838 CERVICAL ESOPHAGEAL WEBS - A ROENTGEN-ANATOMIC CORRELATION.

(E.) Clements, Jr., J. L.; Cox, G. W.; Torres, W. E.; Weens, H. S. (Grady Mem. Hosp., Atlanta, Ga.). *Am. J. Roentgenol Radium Ther. Nucl. Med.* 121(2):221-231, 1974.

Video tape recordings of the proximal or cervical esophagus and pharynx in 100 unselected patients (21 with dysphagia) were examined for the presence of (1) webs or folds, (2) postcricoid impressions, and (3) cricopharyngeal indentations. In addition, the cervical esophagus, trachea, and larynx were removed *en bloc* from 50 unselected cadavers at autopsy for study as anatomic specimens. Webs and folds (thin, shelf-like transverse projections on the anterior mucosal surface of the proximal pharyngoesophageal junction and esophagus) were found in 8 patients (8%), 2 with dysphagia. The webs were also seen in 8 anatomic specimens (16%), 5 from women and 3 from men, aged 30-73 yr, all without a history of dysphagia. Postcricoid impression (a nodular or beak-like impression on the anterior mucosal surface of the cervical esophagus immediately below the level of the cricoid cartilage) was present in 71 patients (71%); 13 of these had dysphagia. In the anatomic specimens, this defect was not demonstrated because clamps during examination obliterated them. Cricopharyngeal indentation

rounded or tongue-like impression found on the
osterior mucosal surface of the cervical esophagus)
ppeared in 18 patients (18%), only 1 of whom had
ysphagia. The anatomic specimens demonstrated 13
f these defects, including 1 specimen with a web
lso present. The histology of esophageal webs and
olds is that of normal mucosa as opposed to the
lummer-Vinson syndrome in which muscular atrophy,
eratinization, or inflammatory changes occur. The
eb is probably of no clinical significance as it
roduces no clinical symptoms. The postcricoid in-
entation is a normal variant unrelated to any par-
icular disorder, but pronounced cricopharyngeal in-
entations may reflect cricopharyngeal abnormality.

339 ESOPHAGEAL PRESSURE STUDIES IN PATIENTS WITH CARCINOMA OF THE ESOPHAGUS. *(E.)*
eschel, H.; Beck, I. T. (Hotel Dieu Hosp., Kingston,
anada). *Can. J. Surg.* 17(4):211-216, 1974.

sophageal pressure studies were performed on 10 pa-
ients (7 men and 3 women, aged 52-90 yr) with car-
inoma of the esophagus. In 6 patients (Group A)
he neoplasm was in the area of the esophagogastric
unction and in 4 (Group B) it involved the body of
he esophagus. Five Group A patients had primary
denocarcinoma of the upper stomach or lower esopha-
us, while 1 had a metastatic intraperitoneal car-
inoma that invaded the esophagogastric junction
rom outside. Three Group B patients had primary
quamous cell tumors and 1 had a metastatic media-
tinal carcinoma encircling the mid-esophagus. No
onsistent motor pattern was detected in the 10 pa-
ients. Motor abnormalities observed in primary and
etastatic carcinoma were not essentially different
rom each other, and differences between groups were
etectable mainly in lower esophageal sphincter func-
ion. The function was abnormal in 3 of 4 Group A
atients studied and normal in all 4 Group B patients.
ne patient in Group A and 2 in Group B had entirely
ormal tracings. An almost consistent finding was
levation of the baseline pressure in the body of
he esophagus (found in 5 Group A and 2 Group B pa-
ients). The elevation was attributed to increased
uscle tone, possibly due to work hypertrophy of the
ortion of the esophagus proximal to the obstructing
arcinoma. Since the esophageal motor pattern of
atients with carcinomas may resemble that of benign
otor dysfunction, motility studies are not helpful
n recognizing carcinoma of the esophagus and may
ead to confusion in diagnosis.

STOMACH

6854 BILE REFLUX GASTRITIS: RESULTS OF SURGICAL THERAPY WITH ROUX-EN-Y GASTROJEJUNOSTOMY.

(E.) Eckstam, E. E.; Scudamore, H. H.; Fencil, W. J.; Jaramillo, C. A. (Monroe Clin., Wis.). *Wis. Med. J.* 73(7):S75-S78, 1974.

Bile reflux-induced gastritis was studied in 20 surgically treated patients and in a larger group of 42, most of whom were medically treated. Surgical procedures performed on the 20 patients were cholecystectomy (10), 3/4 gastric resection (5), vagotomy and pyloroplasty (4), diaphragmatic hernia repair (3), and vagotomy and antrectomy (2). Epigastric pain was present in all patients in each group. Significant numbers of patients also had nausea, vomiting, gas, anorexia, diarrhea, and weight loss. A few had heartburn, dumping syndrome, and dysphagia. The incidence of nausea, vomiting, gas, heartburn, and diarrhea was much higher in the 20 surgically treated patients than in the larger group. Gastric analysis showed that the surgical group had somewhat less acidity. At gastroscopy, superfical gastritis was seen in all and was associated with hypertrophic, atrophic, or erosive gastritis in some. The redness was usually more severe in the resected stomachs, and free bile and bile-stained mucus were seen between the markedly edematous folds. Reflux of bile through the pylorus or stomach was common. X-ray films were of no value in the diagnosis of gastritis. Biopsies confirmed the diagnosis of gastritis and showed an increase in the number of lymphocytes and plasma cells in the lamina propria associated with edema and increased vascularity. Of 20 patients treated with cholestryamine (4 g 4 times/day or 2 g every 2 hr), 10 reported good results, 4 fair, and 6 poor. Results of ulcer therapy in 7 patients were poor. Of 20 patients who underwent a Roux-en-Y anastomosis, 10 are well despite the presence of bile in 4 and 5 are improved, with bile found in 1. The Roux-en-Y procedure was more effective in preventing bile reflux in the 4 patients in whom the length of the gastric limb of the Y was 75 cm, rather than the usual 50 cm. Anastomotic edema was present in the early preoperative period but cleared within 3 months.

6855 NONOBSTRUCTIVE MUCOSAL DIAPHRAGMS OR RINGS OF THE GASTRIC ANTRUM IN ADULTS.

(E.) Ghahremani, G. G. (Med. Coll. Virginia Hosp., Richmond). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 121(2):236-247, 1974.

Nonobstructive antral diaphragm was demonstrated in 6 patients (4 women and 2 men, aged 28-66 yr) seen over a 3-yr period. Five patients presented with a prolonged history of postprandial epigastric pain and sensation of fullness. Symptoms were due to associated hiatal hernia, manifested by a Schatzki's ring in 3 and by a patulous gastroesophageal junction and reflux in 1, duodenal ulcer in 2, and superficial gastric ulcer in 1. Roentgenographic demonstration of antral diaphragm required examination of the relaxed patient in recumbent oblique position, and maximal air-contrast distention of the stomach. The lesion presented as a persistent, sharp, symmetric annular structure dividing the antrum. The diaphragm was 2.0-3.5 mm thick and the diameter of the aperture was 1 cm or more. Premedication with anticholinergic drugs facilitated both roentgenologi and gastroscopic visualization of the lesion. At gastroscopy the antral diaphragm was clearly seen to project into the lumen. The coexistence of Schatzki' ring and antral diaphragm in 3 patients, and the similarities between the 2 lesions, suggests that th antral diaphragm also demarcates the transitional zone of 2 different mucosal linings. Since antral diaphragms with an aperture of 1 cm or greater do not require surgery, treatment was directed toward the associated abnormalities.

6856 ON MEASUREMENT OF BASAL ACID OUTPUT FROM THE STOMACH.

(E.) Malmstrom, J.; Stadil, F.; Rehfeld, J. F. (Rigshosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(4):391-393, 1974.

Spontaneous gastric acid secretion was studied in 52 unoperated patients with dyspeptic complaints and 48 patients with truncal vagotomy and pyloroplasty for duodenal ulcer. The stomach was emptied by aspiration of fasting gastric juice over a 15-min period, and then four 15-min collections were made. In oper ated patients, both acid concentration and acid outp were significantly lower in the last 15-min collecti than in the 1st and 2nd. However, volumes of the fo 15-min collections did not differ significantly. In vagotomized patients, similar but more marked change occurred since acid concentration and output in the last collection were significantly lower than all 3 previous samples. The volume of the last collectio was significantly lower than the first 2 samples bu did not differ from the immediately preceding colle tion. In operated and unoperated patients alike, basal acid output was significantly lower when calculated from the last 30 min samples compared with the samples from the whole 60-min period. The mechanisms responsible for the decreased values with ti are unknown. It is suggested that spontaneous secre tion should be measured over a longer period than th 1 hr customarily employed, especially in postvagoto studies.

6857 GASTRIN LEVELS FOLLOWING THERMAL INJURY.

(E.) Newsome, T. W.; Asch, M. J.;

McGuigan, J. E.; Pruitt, Jr., B. A. (Brooke Army Med. Ctr., Fort Sam Houston, Tex.). *Arch. Surg.* 107(4):622-624, 1973.

Previously, normal levels of gastric acid secretion have been demonstrated in burn patients, even those with Curling ulcer. In the present study, serum gastrin levels were measured serially in 22 patients (18 men and 4 women, 2-68 yr) with burns ranging over 30-90% of body surface. Nine patients developed sepsis, while 3 of the 4 who died had massive upper gastrointestinal bleeding; autopsy showed duodenal ulcers in 2 and gastric ulcer in the 3rd patient. With 2 exceptions (10 and 15 times normal), all patients studied had serum gastrin levels in the normal range but predominantly at the lower end. Although not statistically significant in this small sample, the finding that bleeding occurred in 3 of the 12 patients with serum gastrin levels higher than 50 μμg/ml may be worthy of further study. No correlation was seen between gastrin secretion and magnitude of burn injury, postburn interval, sepsis, or occurrence of gastroduodenal ulceration. By demonstrating that hormonal stimulus for gastric acid secretion is unaltered by burn injury, this study reemphasizes the apparently secondary role of gastric acid in the pathogenesis of Curling ulcer, with the primary role assigned to defects in the barrier function of the gastric mucosa.

6858 GASTRIC JUICE LACTIC ACIDOSIS. THE INCIDENCE OF GASTRIC JUICE LACTIC ACIDOSIS IN GASTRIC CANCER AND BENIGN GASTRIC DISEASE IN COMMUNITIES OF HIGH AND LOW GASTRIC CANCER INCIDENCE. *(E.)* Kasugai, T.; Orwell, R.; Clarke, A. D.; Piper, D. W. (Dept. Med., Univ. Sydney, Australia). *Am. J. Dig. Dis.* 19(7):599-602, 1974.

Excess production of lactic acid is a characteristic feature of gastric carcinoma. To determine the value of this abnormality in detecting patients at risk for gastric cancer, the incidence of gastric juice lactic acidosis in a Japanese population with a high gastric cancer incidence was compared with that of an Australian population with a low incidence. Mean basal lactic acid concentration was higher in the gastric juice of 310 Australian patients than in the gastric juice of 66 Japanese patients without gastric cancer. The proportion of persons with a lactic acid concentration over 100 μg/ml was similar in both groups. Early gastric cancer, studied in 118 Japanese, was associated with increased lactic acid concentration. In advanced cancer, gastric juice lactic acidosis was present in both Japanese and Australian groups, but the 2 populations did not differ with regard to mean lactic acid concentration or to the proportion with concentrations over 100 μg/ml. The progressive increase and severity of gastric juice lactic acidosis observed with advancing cancer suggests that the abnormality may arise from the malignant lesion itself. The higher lactic acid concentrations found in advanced cancer cases probably reflect the increased cell mass in which glycolysis is the major metabolic pathway. Acid output, measured in 61 Australians with gastric ulcer and 38 with gastric carcinoma, showed no correlation with lactic acid concentration, suggesting that atrophic gastritis is not a major determinant of the lactic acid concentration.

6886 HISTOCHEMICAL CHANGES IN GASTRIC MUCOSUBSTANCES IN PATIENTS WITH ACUTE AND CHRONIC ULCER DISEASE. *(E.)* Cathcart, III, R. S.; Fitts, C. T.; McAlhany, J. C.; Spicer, S. S. (Med. Univ. South Carolina, Charleston). *Ann. Surg.* 180(1):1-8, 1974.

Histochemical changes in gastric mucosubstances were studied in 9 patients with gastric ulcer, 16 with duodenal ulcer, 5 with stress ulcer, and 3 with hemorrhagic gastritis. In 2/3 of the specimens, deep foveolar cells produced a slight to moderate amount of a mucosubstance containing sulfate esters and carboxy roups. Mucous neck cells often produced a neutral ucosubstance, but in 1/3 of the patients they formed light to moderate amounts of sulfated mucosubstances nd possibly also carboxyl groups. Chief cells conained sulfated mucosubstance that stained with aldeyde fuchsin even after exposure to testicular hyalronidase; the zymogen granules had no affinity for ther basic dyes but showed weak periodic acid-Schiff eactivity. Mast cells in the gastric mucosa appeard depleted of mucosubstances when compared with hose in the gastric submucosa or the esophagus. hief cells of patients with stress ulcer or hemorhagic gastritis were consistently depleted of sulated microsubstances. In most cases these patients lso showed depletion of the surface epithelial seretion and the presence of interstitial edema in the uperficial mucosa. These findings are consistent ith the view that biosynthetic activity in chief ells and surface epithelial cells is impaired, peraps secondary to shock-induced circulatory changes, n gastric mucosa of patients with stress ulcer or emorrhagic ulcer.

887 ASSOCIATION BETWEEN THE OCCURRENCE OF PEPTIC ULCERS AND TOBACCO SMOKING. *(E.)*

edrychowski, W.; Popiela, T. (Inst. Soc. Med., Krakw, Poland). *Public Health* 88(4):195-200, 1974.

he number of cigarettes smoked daily, the duration f smoking, and the initiation age were studied mong 4,000 males and females chosen at random to xplain the significance of smoking as an element of xternal environment in the genesis of peptic ulcers. ubjects were divided into 3 principal groups: nonmokers, ex-smokers, and current smokers. The latter roup was further divided into 5 subgroups depending n the number of cigarettes smoked daily (from 4/day o 35/day). Peptic ulcers were diagnosed clinically nd by x-ray examination. The relative risk of a eptic ulcer among males was 5 times higher among mokers or ex-smokers. Multiple regression analysis as used to establish the association between the ccurrence of typical peptic ulcer pain syndromes and he factors mentioned above. It was not determined nequivocally whether smoking is causally related to he occurrence of peptic ulcer. The higher frequency f pain symptoms (34.4%) and diagnosed peptic ulcers (13%) among ex-smokers compared with current smokers (27.9% and 11.2% resp.) could be explained by the act that some smokers who had developed the disease n a more acute form gave up smoking. The findings ndicate that the duration of smoking is a stronger actor contributing to peptic ulcer development than he number of cigarettes actually smoked.

888 THE EFFECT OF CIGARETTE SMOKING ON HUMAN GASTRIC SECRETION. *(E.)*

Whitecross, D. P.; Clarke, A. D.; Piper, D. W. (Dept. Med., Univ. Sydney, Australia). *Scand. J. Gastroenterol.* 9(4): 399-403, 1974.

The effect of cigarette smoking on human gastric secretion was studied in 13 control subjects and 8 patients with chronic peptic ulcer. In 1 of 2 tests on controls, gastric juice was collected in 15-min aliquots during 2 hr of continuous suction. In a study performed on both groups, secretion was collected during a basal hour and during a subsequent hour when the subject smoked 4 cigarettes. Response to smoking was expressed as the ratio of the 2nd basal hr or the smoking hr to the 1st basal hr. Smoking did not influence acid, pepsin, or mucus output in controls or peptic ulcer patients. Tar and nicotine content of the cigarettes had no significant influence on the secretory response. Visual assessment of bile concentrations in controls indicated that smoking increased biliary reflux. These findings contrast with an identical study done 15 yr previously when smoking was found to increase gastric acid secretion. The results do correlate with a recent study in which smoking had no effect on ulcer healing. Biliary reflux may influence the apparent secretory response to smoking, and the effect of smoking on secretion may be obscured by the effect of bile salts on the back diffusion of hydrogen ion

6889 PYLORIC REFLUX: A MODIFICATION OF THE TWO-COMPONENT HYPOTHESIS OF GASTRIC SECRETION.

(E.) Hobsley, M. (Middlesex Hosp., London, England). *Clin. Sci. Mol. Med.* 47(2):131-141, 1974.

Gastric juice was obtained during 2-hr maximal stimulation with histamine (0.13 μM/kg/hr i.v.) in 34 controls, 28 patients with duodenal ulcers, and 18 with gastric ulcers. After correction for pyloric losses, the average rate of outputs of water, H^+, Na^+, K^+, and Cl^- were determined. The duodenal ulcer group secreted significantly more gastric juice with significantly greater outputs of H^+ and Cl^- than controls, while the gastric ulcer group secreted significantly smaller amounts of water and these 2 ions. The average K^+ output in each group closely paralleled the rate of secretion of water in that K^+ concentration was similar in all 3 groups: 17.38 mM/liter in controls, 17.72 mM/liter in the duodenal ulcer group, and 17.52 mM/liter in the gastric ulcer group. The duodenal ulcer patients secreted more Na^+ than controls, in about the same proportion as for water excretion; but the gastric ulcer group secreted even more Na^+ despite the smaller water output. The average Na^+ concentration was 13.7 mM/liter in controls, 14.1 mM/liter in duodenal ulcer patients, and 26.2 mM/liter in gastric ulcer patients. Two-component analysis (acid and alkaline) showed the acid component was similar in duodenal ulcer patients and controls, whereas that in gastric ulcer patients was hypotonic and less acid and contained more Na ions. Neither the acid nor alkaline components of gastric juice of gastric ulcer patients could be described in terms of the 2-component theory. Multiple regression analysis suggested that reflux of alkaline liquid from the duodenum is a better explanation of the results than back diffusion of H^+ in exchange for Na^+ between the lumen and wall of the stomach. Reflux appeared to be more important in the gastric ulcer patients than in the other 2 groups.

6890 VAGOTOMY WITH ANTRUM RESECTION. *(E.)*

Svensson, A. (Gavle Hosp., Sweden). *Acta Chir. Scand.* 140(1):50-56, 1974.

Follow-up studies were conducted on 152 of 154 ulcer patients (124 men and 30 women, average age 47 yr) who had undergone Billroth I resection with vagotomy 7-12 yr earlier. Of the entire series, 120 patients had been treated for duodenal ulcers and 38 for juxta-pyloric ulcers. In all cases, the operative procedure involved excision of 1-2 cm of anterior and posterior vagal trunks below the diaphragm. One patient died of renal failure postoperatively following anastomotic leakage. Causes of the remaining 24 deaths were primarily cardiovascular (13) and malignant disease (6), other than carcinoma of the stomach. There was 1 death due to complications of a 2nd operation for recurrent ulcer and 4 deaths due to alcoholism, bronchopneumonia, or accident. Among the 127 patients who were seen personally or who answered questionnaires, 13 (10.2%) had confirmed recurrent ulceration. Another 13 had symptoms of recurrence but no radiological confirmation. About 3% had severe dumping, as classified by Meurling, and 3.9% had severe diarrhea; both complications were more marked in the 11 patients who underwent further surgery for recurrence. Based on hemoglobin standards of 12.5 g% for men and 11.5 g% for women, 7.7% of men and 11.1% of women were anemic. However, 16% of both sexes were iron deficient on the basis of serum iron values and 21% of the men and 32% of the women were anemic according to values for serum transferrin iron saturation. The Schilling test, performed on 99 patients, showed that 24 patients had pathologic or borderline vitamin B_{12} values. Only 1 of the 24 had uniformly low values for the 3 parameters of anemia. While the results of surgery were satisfactory in 75% of men and 71% of women, the study suggests that vagotomy and antrectomy may not be suitable for routine use in ulcer patients.

6891 THE EFFECT OF EXOGENOUS GASTRIN ON THE ACID SHAM FEEDING RESPONSE IN ANTRUM-BULB-RESECTED DUODENAL ULCER PATIENTS. *(E.)* Knutson, U.; Olbe, L. (Sahlgrenska Hosp., Goteborg, Sweden). *Scand. J. Gastroenterol.* 9(3):231-238, 1974.

Physiological vagal activation of gastric acid secretion by 15-min sham feeding was initiated in 6 duodenal ulcer patients after antrum-bulb resection. The sham feeding tests were performed with and without i.v. infusion of pentagastrin in a just suprathreshold dose (0.5 or 1.6 μg/hr). Four of the patients were sham fed both before and after the antrum-bulb resection. In these patients resection reduced peak acid sham feeding response by 51% and maximal acid response to pentagastrin by 42.2%, the latter suggesting a general and irreversible decline in acid-secreting capacity. After resection pentagastrin had only an additive effect on the acid sham feeding response. The results indicate that in duodenal ulcer patients, the sensitivity of parietal cells to cholinergic direct vagal stimulation is maximally facilitated by endogenous gastrin, or other humoral stimuli, originating outside the antrum-bulb area, in contrast to the analogous condition in the dog. The vagally released gastrin from the antrum-bulb area in the duodenal ulcer patient has only an additive secretory effect on acid secretion induced by physiological vagal activation.

6892 LONG TERM RESULTS OF GASTRECTOMY WITH RESPECT TO BLOOD LIPIDS, BLOOD PRESSURE, WEIG AND LIVING HABITS. *(E.)* Glober, G. A.; Rhoades, G. C.; Liu, F.; Kagan, A. (Japan-Hawaii Cancer Study, Honolulu, Hawaii). *Ann. Surg.* 179(6):896-901, 1974.

A total of 347 Japanese-American men who had undergone partial gastrectomy and 7598 Japanese-American men with no history of gastric surgery were compared with respect to selected physiological variables and living habits. Of the partial gastrectomy group, 33.7% had undergone surgery for duodenal ulcer, 58.2 for gastric ulcer, 4.3% for combined duodenal and gastric ulcer, 3.2% for hemorrhagic gastritis, and i only 0.6% was the diagnosis not established. Gastroduodenal anastomoses were performed in 171 (49%) and gastrojejunal anastomoses in 169 (48.7%); 18.2% had vagotomies as well. The gastrectomy subjects weighe an average of 10.5 pounds less than controls and had lower values for serum cholesterol, triglyceride, an blood pressure. There was a statistically, but not clinically, significant difference in hematocrit between groups; none of the gastrectomy subjects had a hematocrit of less than 35%. The depressed lipid an blood pressure values in the surgical group could no be entirely explained by the reduced weight, nor did the physiological differences appear related to diet or living habits. Total alcohol intake did not diff between groups and, while 61.6% of gastrectomy subje were cigarette smokers compared with 42.6% of contro multivariate analysis showed no direct effect of smo ing. Subjects operated on for gastric ulcer had lower systolic pressures than duodenal ulcer patients, and subjects with gastrojejunal anastomoses had lower cholesterol levels than patients with a gastroduodenostomy. The lower serum cholesterol levels in men with a gastrojejunostomy is suggestive of malabsorption; further, in the absence of dietary differences between groups, the reduced weight in surgical cases could be due to malabsorption. It is postulated that partial gastrectomy patients have a significantly reduced risk of myocardial infarction due to their lower weight, cholesterol, triglycerides, and blood pressure.

6893 CHANGES IN THE VOLUME OF CIRCULATING BLOO IN PATIENTS WITH GASTROINTESTINAL BLEEDING. *(Rus.)* Pavlov, V. V. (Odessa Reg. Clin. Hosp. USSR). *Vestn. Khir.* 111(10):12-15, 1973.

Changes in the circulating blood volume were measure by Metholf and Rousellot's dextran technique, the Evan's blue method, and the ^{131}I-labeled albumin met od in 109 patients (85 men and 24 women) hospitalize for acute gastrointestinal bleeding. Bleeding was due to duodenal ulcer in 54 cases, gastric ulcer in 16, erosive gastritis in 17, gastric cancer in 10, portal hypertension in 6, and other causes in 6. Th ^{131}I-labeled albumin technique gave the most accurat information on the circulating blood volume. There was a pronounced circulatory insufficiency in 67 patients admitted within the first 24 hr after onset o bleeding. The volume of circulating blood ranged from 500 to 2000 ml, i.e. from 10 to 40% of normal values. Specific gravity determinations performed on their blood demonstrated that the decrease in cir

ılating blood volume occurred primarily because of
decrease in the red cell volume which accounted
or 65% of the blood loss. Within 24-48 hr after
leeding, hemoglobin values and the RBC decreased
hile the circulating blood volume increased due
o an increase in the plasma volume. The con-
ition of the patient did not always depend on the
mount of blood lost. Collapse, systolic pressures
f 80-85 mm Hg, and weak and unsteady pulses were ob-
erved in 6 patients with little blood loss, while
ome patients who had lost more than 1000 ml had few
linical abnormalities. When transfusions were ad-
inistered, the circulating blood volume did not al-
ays show a corresponding increase. In 56 patients
ropwise i.v. infusion of whole blood increased the
irculating blood volume by only 70% of the volume
f blood administered, while bolus injections of
lood in 36 patients increased circulating blood vol-
mes to 120% of the volume of blood administered.
n both groups of patients increases in the circu-
ating blood volume occurred primarily because of in-
reases in the red cell volume, probably since plas-
a does not remain in the blood stream for a long
ime. Of the 190 patients, 73 (66.1%) responded to
onservative therapy, while 36 (32.9%) had to under-
o surgery. In 29 cases, surgery was delayed for 2-
weeks after bleeding stopped and the circulating
lood volume had returned to normal. Good results
ave recently been obtained by using selective ab-
ominal hypothermia.

894 MEDIUM-TERM FUNCTIONAL AND HISTOLOGICAL
FOLLOW-UP EXAMINATIONS AFTER SELECTIVE
ASTRIC VAGOTOMY. *(Ger.)* Rehner, M.; Soehendra, N.;
itschke, H. (Surg. Clin., Univ. Hamburg, Germany).
tsch. Med. Wochenschr. 98(51):2440-2442, 1973.

ive-yr follow-up examinations were performed on 23
atients who had undergone bilateral selective gast-
ic vagotomy combined with Heineke-Mikulicz pylorop-
asty (16 cases) or a Jaboulay side-to-side gastro-
uodenostomy (7 cases) for duodenal ulcers. Histo-
ogical examination of biopsies taken from the antrum
howed superficial gastritis in 10 cases, superficial
astritis and partial atrophy in 4, and chronic atroph-
c gastritis in 9. Material taken from the corpus
xhibited superficial gastritis in 9 cases, superfi-
ial gastritis with partial atrophy in 4, and chronic
trophic gastritis in only 3 cases. The incidence of
hese changes was about the same as that found in a
ollow-up examination made 1 yr after surgery. After
yloroplasty the pylorus remained wide open and, in
ome cases, slight reflux occurred. With pentagastrin
timulation, acid outputs ranged from 0 to 19.7 mEq/hr
mean 5.6 ± 5.1 mEq/hr) 5 yr after vagotomy. The
uthors conclude that the mucosa undergoes more favor-
ble changes after selective gastric vagotomy than
fter various forms of resection; however, they studied
o patients who had only selective vagotomy or only
arious forms of resection.

895 THE EFFECT OF VAGOTOMY WITH PROCEDURES FA-
CILITATING GASTRIC DRAINAGE ON THE MOTILITY
F BILE DUCTS. *(Pol.)* Dacka, E.; Smajkiewicz, L.
Med. Acad., Lublin, Poland). *Pol. Przegl. Chir.* 45
12):1427-1430, 1973.

Thirty duodenal ulcer patients were examined 3-5 years after having undergone complete vagotomy and one of the procedures facilitating gastric drainage (antrectomy with Rydygier's gastroenterostomy in 10, Reichel-Polya-Finsterer's procedure in 15, pyloroplasty in 3, and gastro-intestinal anastomosis in 2). Cholangiocholecystography was performed on all. In 23 patients a normal radiologic picture of the bile ducts was obtained. After functional tests, the gallbladder contracted to 1/3 of initial size in 22 patients; somewhat weaker gallbladder contractions were noted in only 1 case. An abnormal radiologic picture was obtained in 7 of the 30 patients (23.3%). In 3 cases the gallbladder was large and had lost the ability to contract after ingestion of egg yolks, but the common bile duct and passage of bile into the duodenum were normal. In 4 of the 7 patients the common bile duct was markedly enlarged, while the gallbladder was of normal size and reacted normally to contraction producing stimuli. None of the patients had cholelithiasis. It was concluded that these changes were permanent.

6896 THE "IN SITU" GASTRIC pH IN PRE- AND POST-OPERATIVE INVESTIGATIONS OF PEPTIC ULCER: STUDY OF 206 EXAMINATIONS. *(Fr.)* Boury, G.; Mathey, J. C.; Houdard, C. (Tenon Hosp., Paris, France). *Arch. Fr. Mal. App. Dig.* 63(3):213-222, 1974.

Measurements of the pH of the gastric mucosa were made before and after surgery on 157 patients with gastric or duodenal ulcers and on 15 controls with no evidence of esophageal, gastric, or duodenal disease. The mean age and sex ratios were similar in the 3 groups studied. In 80 patients with duodenal ulcers, the mean intragastric pH before surgery was significantly lower (1.4 ± 0.18) than that found in the controls (1.8 ± 0.2). However, because of dispersion of the results, measurement of the intragastric pH cannot be regarded as a reliable method for diagnosing duodenal ulcers. Before surgery, intragastric pH values in 22 patients with gastric ulcers (1.6 ± 0.2) were intermediate between those in patients with duodenal ulcers and the control group. Surprising little change in the pH occurred after gastroenterostomy alone (1.7 ± 0.4). After gastroenterostomy associated with vagotomy, the postoperative intragastric pH averaged 2.2 ± 1.2. Much larger changes in the intragastric pH were observed after surgery in patients who underwent extensive gastrectomy (5.1 ± 1.4) or antrectomy associated with vagotomy (4.0 ± 1.2). On the basis of these findings and other data in the literature, antrectomy associated with vagotomy is recommended for the treatment of duodenal ulcer since it causes a significant and consistent decrease in gastric acidity and is not accompanied by the sequelae associated with extensive gastrectomy.

6897 BLEEDING DUODENAL ULCER CONTROL. SELECTIVE ARTERIAL EMBOLIZATION WITH AUTOLOGOUS BLOOD CLOT. *(E.)* White, Jr., R. I.; Giargiana, Jr., F. A.; Bell, W. (Johns Hopkins Med. Inst., Baltimore, Md.). *J.A.M.A.* 229(5):546-548, 1974.

SMALL INTESTINE

6912 SMALL INTESTINAL BACTERIAL FLORA IN DERMATITIS HERPETIFORMIS. *(E.)* Heading, R. C.; Parkin, D. M.; Barnetson, R. St. C.; McClelland, D. B. L.; Shearman, D. J. C. (Dept. Therap., Univ. Edinburgh, Scotland). *Am. J. Dig. Dis.* 19(8): 704-708, 1974.

Cultures of jejunal aspirates from 22 patients (aged 25-73 yr) with dermatitis herpetiformis gave bacterial counts of more than 10^6/ml in 11 cases. Of the 22 patients, 12 had an impaired capacity to secrete gastric acid. This may be a further aspect of the many ways in which dermatitis herpetiformis resembles celiac disease. Similar bacteriological profiles were found in the jejunum of the 12 subjects with impaired gastric acid secretion and controls with similarly impaired gastric acid secretion. Thus, colonization of the small intestine in dermatitis herpetiformis is not a primary feature of the condition itself, but can be attributed to the frequently associated impairment of gastric acid secretion. An attempt was made to identify a relation between the flora in patients with dermatitis herpetiformis and the concentration of IgA and IgM in their jejunal aspirates. No evidence for a direct relation was found. Combination of data from patients with hypochlorhydria and those with achlorhydria suggests that the number of organisms may be reciprocally related to both the IgA and IgM concentrations, but the number of patients is too small for this to be statistically substantiated.

6913 MICROBIAL FLORA AND DISACCHARIDASE DEPRESSION IN INFANTILE GASTROENTERITIS. *(E.)*

Barnes, G. L.; Bishop, R. F.; Townley, R. R. W. (Dept. Pediatr., Univ. Melbourne, Victoria, Australia). *Acta Paediatr. Scand.* 63(3):423-426, 1974.

Duodenal disaccharidase activity was studied in 31 infants (22 males and 9 females less than 1 yr) with acute gastroenteritis and normal duodenal mucosal histology. Maltase, sucrase, and lactase levels were compared with normal values of 9.0, 3.5, and 1.1 U/g wet weight, resp., and disaccharidase depression was assumed if levels of at least 2 enzymes were below these norms. Such depression was found in 18 patients, 8 of whom grew *Candida albicans* in abundance in the duodenum. Of the 13 patients with normal disaccharidase activity, only 1 grew *C. albicans* in large numbers. Analysis of individual enzyme levels showed a statistically significant association between lactase depression and growth of *C. albicans*. The incidence of *Escherichia coli* in infants with abnormal disaccharidase levels was the same as in infants with normal enzyme activity. A possible explanation for the association between *C. albicans* and disaccharidase activity is that growth of yeast in the gut lumen reduces enzyme activity at the same level. *C. albicans* strains isolated from infants with gastroenteritis significantly depressed lactase activity when injected into isolated loops of small bowel of infant rabbits.

6914 EFFECT OF SYSTEMIC INFECTIONS ON GLYCYLGLYCINE ABSORPTION RATE FROM THE HUMAN JEJUNUM IN VIVO. *(E.)*

Cook, G. C. (Dept. Med., Univ. Zambia, Lusaka). *Br. J. Nutr.* 32(1):163-167, 1974.

Using a double-lumen tube jejunal perfusion system, the rate of glycine absorption from a glycylglycine solution (50 mM/liter) was measured in 3 groups of Zambian African subjects. In 15 of the subjects (aged 18-61 yr) there was no evidence of infection; 11 subjects (22-58 yr of age) had acute infections and 5 subjects (aged 21-48 yr) had chronic infections. None of these patients had clinical evidence of malnutrition or gastrointestinal disease. Mean glycine absorption rates for the normal group, those with acute infection, and those with chronic systemic infections were 65.7, 60.6, and 68.0 mg/min per 300 mm jejunum, resp. These differences were not significant. Differences in net water transfer from the glycylglycine solution were likewise not significant. Correlation between the glycine absorption rate in individuals and age, body weight, serum albumin, hemoglobin, total globulin, γ-globulin, and the site of the infusion were not significant. These results support earlier findings that, in man, absorption rates of glycine and glycylglycine are influenced differently by acute bacterial infections. These findings provide further evidence that amino acids and peptides use separate transfer mechanisms. It is suggested that protein supplements may be more rapidly absorbed when given as free amino acids than when given as peptides in subjects with acute systemic bacterial infections.

6915 DRUG-INDUCED ENTEROPATHY CHARACTERIZED BY LIPID IN MACROPHAGES. *(E.)*

Gray, J. E.; Weaver, R. N.; Sinkula, A. A.; Schurr, P. E.; Moran, J. (Res. Div., Upjohn Co., Kalamazoo, Mich.). *Toxicol. Appl. Pharmacol.* 27(1):145-157, 1974.

Groups of 10 male Sprague-Dawley rats were treated p.o. for 1 week with the synthetic 2'-dodecyl glutaramide ester of erythromycin. Rats given 1000 mg/kg/day ate about 1/2 of normal food consumption and showed essentially no growth. Weight gains of rats given 300 and 500 mg/kg were proportionally less affected. No gross lesions were observed. Lipid droplets accumulated in macrophages and in the lamina propria of the small intestine and in the sinusoids of the mesenteric lymph nodes, in Kupffer cells in the liver, and in fixed macrophages in the spleen. In fixed frozen sections, these droplets stained well with Oil Red O. Toluidine blue-stained epoxy sections were most useful in studying the distribution of the droplets. Paraffin sections showed no evidence of acid-fastness or autofluorescence. The droplets resembled neutral lipid under electron microscopic examination. They appeared to undergo a gradual membranous degradation at their surface; most of the droplets had disappeared at 3 weeks post-treatment. Small aggregated myeloid figures were also present in the cells of the lamina propria of the small intestine and occasionally in the absorptive cells. Parallel studies with erythromycin base (659 mg/kg) and the 2'-dodecyl glutaramide moiety (342 mg/kg) did not produce the lipid accumulation in macrophages. From these results, it was concluded that the ester was absorbed unhydrolyzed and converted rapidly to a chylomicron-like droplet. The reduction of p.o. D-xylose in urine to about 1/4 of that in control rats was suggestive of malabsorption. Steatorrhea could not be confirmed by fecal lipid analyses due to the lipid structure of the ester.

6916 MORPHOLOGY, DIPEPTIDASES AND DISACCHARIDASES OF SMALL INTESTINAL MUCOSA IN CHRONIC RENAL FAILURE. *(E.)*

Denneberg, T.; Lindberg, T.; Berg, N. O.; Dahlquist, A. (Malmo Gen. Hosp., Sweden). *Acta Med. Scand.* 195:465-470, 1974.

Small intestinal function was studied in 29 patients (13 women and 16 men, aged 19-69 yr) with chronic renal failure. Of these patients, 18 were on regular hemodialysis, 9 had uremia, and 2 a nephrotic syndrome. Morphologic examination of 19 small intestinal biopsies showed pronounced changes in 6 patients (ridging, crypt elongation, and heavy plasma cell infiltration) but only slight changes in the others. Enzyme activity was more affected than the morphology of the intestinal mucosa. Fourteen biopsies had decreased sucrase and maltase activity and 10 had low glycyl-L-leucine and L-alanyl L-proline dipeptidase activities. Only 2 patients had normal dipeptidase and disaccharidase activities. Pancreatic function, tested in 5 patients, was normal. The dysfunction of the small intestine was also reflected in the increased fecal fat excretion in 4 of 14 patients tested, low serum folate in 8 of 20 (before dialysis), and general flattening of the glucose tolerance curve in dialysis and uremic patients. The reduced sucrase and maltase activity may create gastrointestinal difficulties with carbohydrate-rich diets, but the depression of dipeptidase activity was not great enough to interfere with peptide absorption. The 2 patients with nephrotic syndrome had normal morphology in biopsy specimens and practically normal enzyme activities. No characteristic finding was registered for other renal diseases, although both biopsied patients with Alport's syndrome had a distinct increase of plasma cells and elongation of crypts. The finding of uremic enteropathy in most of these patients suggests that the entire gastrointestinal tract is involved in chronic renal failure.

6917 INFLAMMATORY PSEUDOTUMOR OF THE SMALL INTESTINE. *(E.)* Campbell, W. L.; Green, W. M.; Seaman, W. B. (Coll. Physicians Surg., New York, N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 121(2):305-311, 1974.

Case reports are presented for 6 patients (3 women and 3 men, aged 49-62 yr) with inflammatory pseudotumor of the small intestine. Roentgenographically, the lesion was a submucosal mass localized in the 1st portion of the duodenum in 1 patient, in the duodenal bulb on old duodenal ulcer scars in 2, and in the ileum in 3. The ileal pseudotumors intussuscepted and caused obstruction, with the lumen almost obliterated in 1 case. Mass size ranged from less than 1 cm in diameter to 4.5 X 11 cm. Large inflammatory pseudotumors simulated benign neoplasms. Histologically, the submucosal masses were characterized by inflamed granulation tissue with variable numbers of eosinophils; some lesions had virtually no eosinophils. In contrast to eosinophilic gastroenteritis, inflammatory pseudotumor is a well-defined lesion and is not associated with clinical allergies and increased numbers of blood eosinophils.

6918 NEOPLASMS OF THE SMALL BOWEL. *(E.)* Silberman, H.; Crichlow, R. W.; Caplan, H. S. (USAF Med. Ctr., Scott AFB, Ill.). *Ann. Surg.* 180(2):157-161, 1974.

Thirty-two malignant and 34 benign neoplasms of the small intestine were diagnosed over a 20-yr period. Patients with malignant lesions averaged 56.8 yr at diagnosis compared with 62.2 yr for patients with benign lesions. Malignant lesions were divided equally between men and women, but 23 of the 34 benign lesions were in men. Nearly all (30) of the 32 patients with malignancies were symptomatic, whereas in 1/2 of the patients with benign lesions the condition was an incidental finding. The most common symptoms of small bowel malignancy were weight loss (17 cases), pain (15 cases), anemia (13 cases), nausea (11 cases), and palpable mass (7 cases). Among symptomatic patients with benign tumors, pain occurred in 14 and rectal bleeding in 10. Small-bowel radiography was the most useful diagnostic aid. Histologically, the malignant tumors were adenocarcinoma (19), carcinoid (8), leiomyosarcoma (4), and lymphosarcoma (1). Over 1/2 the adenocarcinomas were duodenal and 3/4 of the carcinoids were located in the ileum. Nine types of benign lesions were identified, but leiomyomas and benign carcinoids accounted for 1/3 of the lesions. Of the 10 benign carcinoids, 9 were in the ileum. Thirteen patients, including 7 with carcinoid tumors, had 14 other primary tumors outside the bowel. Resection in 25 of 32 cases of malignant tumors resulted in eight 5-yr survivals. These survivors included 3 with adenocarcinoma, 3 with malignant carcinoid, and 1 each with leiomyosarcoma and lymphosarcoma.

6919 PRIMARY MALIGNANCIES OF THE SMALL BOWEL: A REPORT OF 96 CASES AND REVIEW OF THE LITERATURE. *(E.)* Wilson, J. M.; Melvin, D. B.; Gray, G. F.; Thorbjarnarson, B. (N. Y. Hosp.-Cornell Med. Ctr., New York, N.Y.). *Ann. Surg.* 180(2):175-179, 1974.

The clinical records and histological sections of 96 patients (51 men and 45 women, aged 31-84 yr) with primary small bowel malignancies were reviewed for the period 1932-1972. There were 48 adenocarcinomas, 37 carcinoids, and 11 leiomyosarcomas. The peak incidence of adenocarcinoma was in the 7th decade while the other 2 types of tumors were more common in the 6th decade. Only 7 malignant small intestinal tumors occurred in patients younger than 30 yr. The average duration of symptoms was 6 months for adenocarcinoma, 8 months for leiomyosarcomas, and 12 months for carcinoids. The most common presentation was pain (33%) followed by weight loss (23%), obstruction (16%), hemorrhage (15%), jaundice (5%), intussusception (3%), and perforation (3%). Masses were felt in 30% of the cases but were usually dilated bowel or intussusception rather than the tumor *per se*. Eighty-four patients (88%) had symptoms leading to an operative diagnosis, and curative resection was attempted in 80 of these; 12 carcinoids were diagnosed at autopsy. Of the 48 patients with carcinoma, 6 (15%) were alive after 5 yr. Three of these had pancreatico duodenectomy for duodenal tumors, and 3 had wide excision of jejunal lesions. Seven of the 37 patients with carcinoids and 2 of 11 with leiomyosarcomas were alive at 5 yr. The 80% mortality among patients followed for 5 yr is attributed to the late appearance of symptoms and anatomic obstacles to a truly radical operation. In the case of adenocarcinomas and carcinoids, such an operation would require sacrifice of nearly all the small intestine and proximal colon.

6920 PERFORATED DIVERTICULITIS OF THE TERMINAL ILEUM. *(E.)* Ackerman, N. B. (Menorah Med. Ctr., Kansas City, Mo.). *Am. J. Surg.* 128(3):426-428, 1974.

erforated diverticulitis of the terminal ileum was
ocumented in a 63-yr-old woman who presented with
cute abdominal pain, nausea, and lower abdominal
enderness. The blood cell count on admission in-
luded a hemoglobin of 11.4 g% and a WBC of 5800/mm^3
ith 74% polymorphonuclear leukocytes. Over the next
ew days the WBC rose to 10,400/mm^3 with 81% poly-
orphonuclear leukocytes. Since the patient's his-
ory included an appendectomy and a barium study sug-
esting diverticular disease of the descending colon,
he preoperative diagnosis was diverticulitis of the
igmoid colon. However, laparatomy revealed a hard
odular mass that involved the terminal ileum, cecum,
nd mesentery. Primary resection with ileotransverse
olostomy was performed because malignancy was sus-
ected. The surgical specimen showed multiple diver-
icula in the terminal ileum, with a large walled-off
bscess communicating with 1 perforated diverticulum.
he diverticula were all located on the mesenteric
order. The patient died on the 8th postoperative
ay from cardiopulmonary disease. At autopsy multiple
iverticula of the jejunum and remaining ileum were
ound along the line of mesenteric attachment; no
iverticula were seen in the large intestine. Of the
previous cases of perforated diverticula of the
erminal ileum reported in the English literature,
he patient died postoperatively, presumably from
verwhelming sepsis. Two developed postoperative
omplications consisting of a wound infection and
istula in 1 and a pelvic abscess in the other. Al-
hough rare, perforated diverticulitis of the terminal
leum should be considered when a patient presents
ith an ileocecal mass at operation. Primary resec-
ion with ileotransverse colostomy is probably the
reatment of choice although associated with a signi-
icant mortality and morbidity.

921 INTRALUMINAL DUODENAL DIVERTICULUM. *(E.)*

Yang, T. S.; Greenspan, A.; Farber, M.;
ichter, R. M.; Bryk, D.; Levowitz, B. S. (Jewish
osp. Med. Ctr., Brooklyn, N. Y.). *Arch. Surg.* 109
l):113-115, 1974.

ntraluminal duodenal diverticulum was diagnosed pre-
peratively by roentgenographic study in a 45-yr-old
oman with a 6-month history of intermittent gastric
ain and fullness. Roentgenographic findings were
hose of an elongated barium collection entirely
ithin the duodenal lumen, surrounded by a narrow
adiolucent line. By abolishing peristalsis, hypo-
onic duodenography (60 mg propantheline bromide i.m.)
emonstrated the radiolucent septum traversing the
uodenal lumen as the basic abnormality. The diver-
icular wall was excised through a duodenotomy, with
losure of the mucosal defect by direct approxima-
ion. Injury of the common bile duct was avoided
 inserting a probe *via* a choledochtomy incision
hrough the papilla of Vater prior to excision. It
s suggested that intraluminal duodenal diverticulum
s caused by incomplete recanalization of the embry-
nic duodenal lumen after its obliteration by epi-
helial cell proliferation. In the event of faulty
ecanalization, a diaphragm results that may vary
rom a completely obstructing imperforate web to a
mall membrane attached along a short portion of the
uodenal circumference. Such a membrane may flatten
out against the duodenal wall when subjected to continual peristalsis, or similarly elongate and produce the type of diverticulum reported in this patient. If the duodenum is obstructed and duodenojejunostomy is elected, care must be taken in the choice of the site for the duodenal opening. In adults with longstanding duodenal obstruction and dilation, proximal diversion may be preferable to excision of the diaphragm. When the duodenum fails to recover its tone and normal peristaltic ability after decompression, gastrojejunostomy or Billroth II gastric resection may give relief if biliary and pancreatic secretions enter the duodenum distal to the level of obstruction. If the papilla of Vater is proximal to the obstruction, direct excision of the membrane is the only alternative.

6922 VALUE OF SELECTIVE AND TRUNCAL VAGOTOMY IN MASSIVE BOWEL RESECTION. *(E.)*

Albo, R. J.; Angotti, D.; Sorensen, D.; Michaels, T. A. (Highland Gen. Hosp., Oakland, Calif.). *Am. J. Surg.* 128(2): 234-242, 1974.

To determine whether vagotomy would decrease the high mortality after massive bowel resection and to clarify whether preservation of the vagal branches to the liver, pancreas, and small bowel (selective vagotomy) would enhance the survival and produce an anabolic effect, selective vagotomy and pyloroplasty was compared with truncal vagotomy and pyloroplasty in mongrel dogs subjected to massive bowel resection. Alterations in absorption of ingested proteins, carbohydrates, and fat and changes in intestinal transit time were studied as possible means for showing the effects of vagotomy. Selective and truncal vagotomy and pyloroplasty increased the survival time and decreased the percent of daily weight loss in the dogs when compared with massive bowel resection only. No significant difference in survival time was noted between selective vagotomy and truncal vagotomy. Vagotomy and pyloroplasty also increased the absorption of nitrogen and fat and lengthened the transit time when compared with massive bowel resection only, but an anabolic state was not created and the operative procedure did not represent the entire solution for a patient with massive bowel resection. It is suggested that the adjunctive procedure be delayed until after a period of observation with good medical management had been determined to be unsuccessful.

6923 CURRENT ASPECTS OF INTESTINAL TUBERCULOSIS: REVIEW OF 12 CASES AND THE RECENT LITERATURE. *(Fr.)*

Legre, M.; Boucher, J. (Hopital de la Conception, Marseille, France). *Ann. Gastroenterol. Hepatol. (Paris)* 9(5):435-455, 1973.

On the basis of 720 cases reported in the literature since 1960 and 12 of their own cases, the authors propose a system for classifying intestinal tuberculosis into 3 groups. These consist of (1) early primary, or apparently primary forms which most often respond to drug therapy; (2) late forms which are generally sequelae and must often be treated surgically because of mechanical complications; and (3) classical forms secondary to pulmonary tuberculosis which have developed recently and are progressive in nature. Of the authors' 12 patients (7 women and 5 men, aged 25-75 yr), 5 belonged to group (1). The principle problem in this group was of establishing a differential diagnosis between intestinal tuberculosis and Crohn's disease. Pulmonary tuberculosis was diagnosed in 3 of these 5 patients. Drug treatment was successful in 3 cases, but 1 patient developed a pulmonary and peritoneal recurrence 4 yr later. Right hemicolectomies were performed on the remaining 2 patients who were then given antibiotics. Of the 5 patients in group (2), 4 had histories of pulmonary tuberculosis and 1 had undergone an appendectomy 13 yr previously when tubercular lesions were found. A right hemicolectomy was performed on 1 of these 5 patients. Of the 2 patients in group (3), both had histories of pulmonary tuberculosis; 1 patient died.

6924 GASTROINTESTINAL MANIFESTATIONS OF URTICARIA PIGMENTOSA. *(Fr.)* Debray, C.; Leymarios, J.; Cerf, M.; Marche, C.; Bocquet, L. (Bichat Hosp., Paris France). *Ann. Med. Interne (Paris)* 124(12):927-930, 1973.

A 46-yr-old man with a 2-yr history of diarrhea and Darier's sign presented with hepatosplenomegaly. A diagnosis of urticaria pigmentosa was confirmed by a skin biopsy. At laparoscopy, diffuse hepatic hypertrophy was seen with no evidence of nodules, but liver function tests were normal. Radiological examinations showed many round, clearly defined filling defects in the duodenal bulb with a few small ones in the colon and stomach; the jejunal folds were thickened. Other findings included decreased IgA levels in jejunal fluid and saliva, bone condensation, anemia, and mast cells in a bone marrow biopsy. Biological tests for intestinal malabsorption were negative, and jejunal lactase activity was within normal limits. Microscopic examination of jejunal biopsies revealed partial or subtotal villous atrophy with moderate fibrosis and infiltrates of lymphocytes, plasma cells, and polynuclear eosinophils in the lamina propria; the number of mast cells was normal. Ultrastructural examinations of the jejunum showed epithelial damage, particularly to microvilli in villous enterocytes, and membrane degradation in the cytoplasm of plasma cells. At autopsy, 2 yr after the initial hospitalization, mast cell proliferation was found in the heart, abdominal lymph nodes, bone marrow, spleen, and liver. Except for a polyadenoma of the colon, no mast cell proliferation was observed in the intestinal mucosa.

6925 SUBCLINICAL OR MASKED CASES OF CHRONIC MESENTERIC ISCHEMIA. *(Fr.)* Patrassi, G.; Zuin, R. (Med. Clin., Univ. Padua, Italy). *Ann. Gastroenterol. Hepatol.* 9(3):223-235, 1973.

Chronic mesenteric ischemia in 2 patients was diagnosed by aortography. A 30-yr-old man with a history of myocardial infarction developed episodes of abdominal pain which were alleviated only by fasting for 24-48 hr. The patient was variously diagnosed as having spastic colitis, irritable colon, and a gastric ulcer and lost 22 kg in about 1 yr. Abdominal aortography showed obstruction of the celiac trunk and superior mesentery and very slight stenosis of the right common iliac artery. Good results were obtained with a superior aortomesenteric bypass and reversal of a segment of the great saphenous vein. A 62-yr-old alcoholic with a 9-yr history of mild diabetes mellitus developed episodes of abdominal pain lasting 10-15 min which often occurred after he had eaten cold food. He developed steatorrhe and progressive weight loss. Liver biopsies showed associated cirrhotic perihepatitis, and radiological examinations demonstrated calcification of the pancreas and abdominal aorta. Aortography demonstrated annular retraction of the gastrohepatic artery and a pronounced reduction in the diameter of the superior mesenteric artery with Riolan's arch originating in the inferior mesenteric artery. The slow course of the disease in this case suggests that arterial disease was an important factor in the development of chronic pancreatitis and diabetes. If pancreatitis had produced the arterial obstruction, arteria changes would have been more localized. It is recommended that aortography be used for patients with chronic pancreatitis, especially when no convincing cause for the pancreatitis can be established.

SMALL INTESTINE

Malabsorption

945 A ROENTGENOGRAPHIC CLASSIFICATION OF DIFFUSE DISEASES OF THE SMALL INTESTINE PRE-ENTING WITH MALABSORPTION. *(E.)* Tully, T. E.; einberg, S. B. (Dept. Diag. Radiol., Univ. Minne-ota, Minneapolis). *Am. J. Roentgenol. Radium Ther. ucl. Med.* 121(2):283-290, 1974.

evelopment of peroral biopsy techniques, use of olloidal barium in roentgen examination, and fiber-ptic endoscopy have permitted accurate clinical nd pathologic descriptions of diffuse diseases of he small intestine presenting with malabsorption. proposed 4-part classification for the malabsorption spectrum of diseases is based on the presence or absence of dilation as well as thickness and regularity of the mucosal fold pattern, as determined by small bowel roentgen examination. The various diffuse lesions are grouped as follows: (I) normal small intestine pattern, (II) dilated small intestine with normal folds, (III) thickened regular folds with or without dilatation, and (IV) thickened irregular or nodular folds with or without dilatation. Correlation of these patterns with small bowel biopsy, clinical findings, and simple laboratory methods usually indicates a definite diagnosis. Data processing and computer analysis should be the next step in the application of this classification.

6946 THE FOLATE CONJUGASE ACTIVITY OF THE INTESTINAL MUCOSA IN CELIAC DISEASE. *(E.)*

Jagerstad, M.; Lindstrand, K.; Norden, A.; Westesson, A. K.; Lindberg, T. (Univ. Hosp., Lund, Sweden). *J. Gastroenterol.* 9(3):255-259, 1974.

Folate conjugase activity was compared in small intestinal biopsies from 16 patients with celiac disease and 43 controls with normal intestinal mucosa. Conjugase activity, expressed as ng of mono- and/or diglutamic folate released/mg protein during 10 min, was markedly higher in the flat mucosa of celiac disease than in biopsies with a normal villous structure. The difference in enzyme activity did not reflect a difference in methylation ability: there were no significant differences in folic acid recovery, estimated with *L. casei* and *S. faecelis*, between or within the celiac and control groups. To determine the degree to which inflammatory cells contribute to conjugase activity, leucocytes from normal blood were isolated and further fractionated into lymphocytes and granulocytes. Leukocytes had a folate conjugase activity/mg protein 4 times higher than normal biopsies. All activity was localized in the granulocyte fraction.

6947 THE JEJUNAL CELLULAR INFILTRATE IN COELIAC DISEASE COMPLICATED BY LYMPHOMA. *(E.)*

Ferguson, R.; Asquith, P.; Cooke, W. T. (Gen. Hosp., Birmingham, England). *Gut* 15(6):458-461, 1974.

Lymphocytes and plasma cells in the lamina propria and lymphocytes in the epithelium were quantitated in jejunal biopsies from 18 patients with celiac disease and confirmed lymphoma. Of these patients, 14 were on a normal diet. Counts were compared with those obtained in 15 healthy controls and 30 patients with uncomplicated celiac disease, including 15 on a normal diet and 15 on a gluten-free diet for more than 1 yr. Patients with lymphoma had decreased mean cell counts compared with the other 2 celiac groups and increased mean cell counts compared with controls. The lymphoma patients differed from untreated celiacs in that they had significantly lower plasma cell and significantly higher lymphocyte counts in the lamina propria and significantly lower lymphocyte counts in the epithelium. Differences in cell counts between the lymphoma patients and the celiac patients on a gluten-free diet were not significant. The changes found in 6 of the lymphoma patients were present in biopsies counted up to 5 yr before the diagnosis of lymphoma. The results suggest that the immunological status of celiac patients with lymphoma differs from that of other celiacs and could represent a primary abnormality. Consequently, plasma cell and intraepithelial lymphocyte counts might indicate those celiac patients who are prone to develop malignancy.

6948 CHANGES IN PLASMA FREE FATTY ACID CONCENTRATION FOLLOWING ORAL LACTOSE TOLERANCE TESTS AS A TEST FOR LACTOSE ABSORPTION IN INFANTS AND CHILDREN. *(E.)*

Tamir, I.; Levtow, O.; Dolizki, F.; Werbin, B. (Rokach Hosp., Tel Aviv, Israel). *Am. J. Dig. Dis.* 19(8):745-750, 1974.

Changes in blood glucose and plasma free fatty acid following oral lactose tolerance tests were measured in 3 groups of children. Of 17 infants, aged 1-16 months, with secondary lactose intolerance, 3 showed a small increase (less than 25 mg/100 ml) in glucose levels, but a normal decline of more than 50% from the fasting value in the free fatty acid concentration. When milk feeding was resumed, it became obvious that they were not intolerant to lactose. Of 16 infants, aged 2-21 months, with acute gastroenteritis but no evidence of intolerance to dietary sugar, 6 showed only small increases in glucose and 5 of the 6 showed a normal decline in plasma free fatty acids. The 3rd group consisted of 19 children, aged 2.5-14.5 yr, undergoing investigation due to growth retardation. In 6 of these 19 children, clinical symptoms of lactose intolerance developed after the oral lactose tolerance tests. In all 6, a flat glucose curve and a decline of less than 50% in plasma free fatty acids was noted. These patients were diagnosed as lactose intolerant. Of the remaining 13 children, none showed evidence of lactose intolerance. In 9 of them a flat glucose curve was obtained, but only 1 of the 13 had no decline in plasma free fatty acids. Based on blood glucose levels in this study, 37% of the children with lactose intolerance secondary to acute gastroenteritis and 47% of the children without lactose intolerance would have been incorrectly diagnosed on the basis of changes in plasma free fatty acids. It is suggested that a decline in free fatty acids of 50% or more from the fasting level 30 or 60 min after ingestion of lactose be accepted as an indicator of normal hydrolysis and absorption of lactose.

6949 DISACCHARIDASE ACTIVITY IN THE SMALL INTESTINAL MUCOSA IN CASES WITH ACUTE ENTERITIS. *(E.)*

Gudmand Hoyer, E.; Soeberg, B. (Blegdams Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(4):405-409, 1974.

Disaccharidase activity was measured in biopsies from the small intestine of patients (5 females and 6 males, aged 18-70 yr) with acute enteritis. Biopsies were taken in the acute phase and at least 3 months after recovery. On the whole, transient lowering of the lactase activity was encountered, and in 2 patients values corresponding to lactose malabsorption were found. The activity of the remaining enzymes was unaffected, although diffuse reduction of the lactase activity was found in 2 patients with subtotal atrophy of the villi. In the remaining 9 patients, only uncharacteristic histological changes could be observed. Even excluding the 2 patients with subtotal villous atrophy, the lactase activity during acute enteritis was significantly reduced, indicating that lactase is the enzyme most sensitive to lesions of the small intestinal mucosa. Thus, a lactase determination is a more indicative measurement of such difficulties than a histological examination. The fact that persistent lactase deficiency may result from tropical sprue and kwashiorkor, in spite of sufficient treatment and normalization of the intestinal mucosa, supports the concept of lactase as the most vulnerable enzyme.

950 JEJUNAL ABSORPTION AND SECRETION OF CALCIUM
IN PATIENTS WITH CHRONIC RENAL DISEASE ON
EMODIALYSIS. *(E.)* Parker, T. F.; Vergne-Marini, P;
ull, A. R.; Pak, C. Y. C.; Fordtran, J. S. (Univ.
exas Southwestern Med. Sch., Dallas). *J. Clin.
nvest.* 54(2):358-365, 1974.

en patients with chronic end-stage renal disease on
emodialysis and 8 normal controls were studied by
onstant jejunal perfusion of calcium gluconate so-
utions (11 ml/min for 1 hr after 3/4 hr for equili-
ration) using 0.5% polyethylene glycol as a non-
bsorbable marker. Solutions isosmotic to blood
lasma contained 0, 1, 5, 15, and 20 mM calcium gluc-
nate. Results in normals indicated that calcium
bsorption from 1 and 5 mM calcium solutions is mainly
ctive. Absorption from 5, 15, and 20 mM solutions
as a linear function of luminal calcium concentra-
ion, suggesting that the active transport carrier
s saturated when luminal calcium concentration is
reater than 5 mM and indicating that the increment
n absorption at higher luminal concentrations is
ainly the result of passive absorption. With 1 mM
alcium, normals absorbed calcium against a concen-
ration gradient, whereas the patients secreted cal-
ium. Absorption in the patients was much less than
ormal with 5, 15, and 20 mM luminal calcium concen-
rations; however, the slope of this linear (passive)
ortion of the curve was normal. Unidirectional cal-
ium fluxes were measured with ^{47}Ca. Flux out of the
umen was depressed 2.5-fold in the patients, but
lux into the lumen was normal. Xylose, urea, and
ritiated water were absorbed normally, indicating
o generalized abnormality of jejunal transport in
hese patients. Endogenous calcium secretion, esti-
ated by the amount of calcium added to a calcium-
ree solution, was normal in the dialysis patients.
hese results indicate that active calcium absorption
s markedly depressed in patients with chronic renal
isease who are receiving hemodialysis therapy. On
he other hand, passive calcium movement and endogen-
us calcium secretions are normal.

951 JEJUNAL CALCIUM TRANSPORT IN HEALTH AND
METABOLIC BONE DISEASE: EFFECT OF VITA-
IN D. *(E.)* Soergel, K. H.; Mueller, K. H.; Gustke,
. F.; Geenen, J. E. (Med. Coll. Wisconsin, Milwau-
ee). *Gastroenterology* 67(1):28-34, 1974.

et absorption and unidirectional fluxes of calcium
ere determined by continuous intestinal perfusion
f a 30-cm segment of proximal jejunum on 24 occa-
ions in 12 children. The test solution contained
alcium gluconate (2.5 mM/liter) and radioactive ^{47}Ca.
he subjects included 5 patients with sporadic vita-
in D-resistant rickets and 1 each with florid nutri-
ional rickets and with acute disuse osteoporosis.
n controls, the bidirectional calcium flux across
he luminal cell wall of the absorbing epithelium was
mall in magnitude. Jejunal calcium absorption was
ecreased in all untreated patients; in 5 cases, this
as attributable to a reduction in mucosal calcium
ptake, but 2 patients with vitamin D-resistant rick-
ts demonstrated an unexpected increase in calcium
lux in the reverse direction. Therapy with vitamin
2 (25,000-100,000 U/day p.o.) invariably resulted in accelerated net calcium absorption without changes in net transport of water, sodium, chloride, and potassium, and in flow rate and calcium content of fasting intestinal contents. A linear correlation existed between a jejunal net calcium absorption and net calcium absorption determined in 22 preceding metabolic balance studies. Jejunal net calcium absorption of less than 3 μM/hr/cm correctly separated patients with untreated metabolic bone disease from treated patients and controls on 22 of 23 occasions. Jejunal calcium absorption, determined by steady-state intestinal perfusion, was a reliable and convenient indicator of tocal calcium balance in this group of children.

6952 LUMINAL EVENTS OF LIPID ABSORPTION IN PROTEIN-CALORIE MALNOURISHED CHILDREN; RELATIONSHIP WITH NUTRITIONAL RECOVERY AND DIARRHEA. I. CAPACITY OF THE DUODENAL CONTENT TO ACHIEVE MICELLAR SOLUBILIZATION OF LIPIDS. *(E.)* Schneider, R. E.; Viteri, F. E. (Inst. Nutr. Central America Panama, Guatemala City, Guatemala). *Am. J. Clin. Nutr.* 27(8):777-787, 1974.

Fat absorption and the capacity of the duodenal content to achieve micellar solubilization of lipids was studied in 18 severely protein-calorie malnourished children (aged 15-70 months) on admission and at different stages of nutritional recovery. Four healthy children (aged 17-23 months) served as controls. The micellar lipid concentration in duodenal aspirates was 6.60 mg/ml in controls, compared with 0.86 mg/ml in patients with diarrhea and 2.81 mg/ml in patients without diarrhea. In children without diarrhea, micellar lipid increased with nutritional recovery and ultimately reached normal values. Diarrhea hampered this improvement and was associated with larger amounts of duodenal aspirates in 90 min and higher dilution of the emulsion. Fat absorption was normal (greater than 90% of intake) only in recovered or recovering children without diarrhea and with micellar lipid concentrations greater than 4 mg/ml. Regardless of the degree of protein repletion, none of the children with diarrhea had normal fat absorption. Stepwise regression analysis showed that conjugated bile acids accounted for 36% of the observed variation in micellar lipid, while free bile acids and lipase activity each accounted for 8%. Dilution and nitrogen accounted, resp., for 0.8 and 0.2% of the variability. Although micellar lipid rose as conjugated bile acid concentration increased, a discrete but opposite trend was observed with free bile acids. It is concluded that conjugated bile acids and an elevation in the ratio of free bile acids to conjugated bile acids plays an important role in decreasing micellar lipid capacity and lipid absorption in children with protein-calorie malnutrition or diarrhea.

6953 LUMINAL EVENTS OF LIPID ABSORPTION IN PROTEIN-CALORIE MALNOURISHED CHILDREN; RELATIONSHIP WITH NUTRITIONAL RECOVERY AND DIARRHEA. II. ALTERATIONS IN BILE ACID CONTENT OF DUODENAL ASPIRATES. *(E.)* Schneider, R. E.; Viteri, F. E. (Inst. Nutr. Central America Panama, Guatemala City, Guatemala). *Am. J. Clin. Nutr.* 27(8):788-796, 1974.

Duodenal aspirates from 18 children with protein-calorie malnutrition, with or without diarrhea, were analyzed for quantitative and qualitative alterations in bile acids. Data were obtained on admission and during nutritional recovery. Compared with 4 healthy controls, children with protein-calorie malnutrition had significantly decreased concentrations of conjugated bile acids and significantly increased amounts of primary and secondary free bile acids. In the absence of diarrhea, protein-calorie malnutrition was associated with relatively uniform decrements of conjugated bile acids, which returned to normal levels with nutritional recovery. The amounts of primary and secondary free bile acids did not change significantly with recovery. Recovered children with diarrhea did not attain the normal levels of conjugated bile acids noted in recovered children without diarrhea. This was due primarily to decreased amounts of both glyco- and taurocholate, but especially to the taurocholate decrement. The glycine/taurine ratio was therefore higher in recovered children with diarrhea than in any other group, although the differences were not significant. While all free bile acids increased in recovered children with diarrhea, the most significant increases were in cholic and lithocholic acids. Levels of primary and secondary free bile acids were similar in malnourished children with and without diarrhea. It is concluded that the observed alterations in bile acids were due to the interaction of malnutrition, diarrhea, and bacterial degradation (i.e., deconjugation and dehydroxylation) of bile acids in the intestinal lumen.

LARGE INTESTINE

74 RECURRENCE OF CARCINOMA OF THE LARGE INTESTINE: A STATISTICAL REVIEW. *(E.)*
indo, K. (Osaka Univ. Hosp., Japan). *Am. J. Proc-
l* 25(3):80-90, 1974.

statistical analysis was conducted on 2,299 autopsy
ses and 116 surgical cases of recurrence from col-
ectal cancers. In 85% of the cases, recurrences
curred within 3 yr after radical operation. Rectal
rcinoma metastasized to the liver in 47% and to the
lvis in the same percentage of cases. Colonic can-
r metastasized to the liver in 51% of the cases.
lmonary metastases occurred in 39% of rectal and
31% of colonic carcinomas. Of the patients with
ng metastases, 71% also had liver metastases.
inically demonstrated local recurrences were found
57% of the cases. Ascites was noted in the ter-
nal stage of recurrence due to peritoneal carci-
matosis, carcinogenic hypoproteinemia, and portal
pertension from compression. Palliative treatment
nsisting of blood or plasma transfusions, diuretics,
d i.p. infusion of anticancer agents is recommended.
e selective intraarterial infusion of 5-fluorouracil
recommended for management of colorectal cancer.
ltiple recurrent lesions may be treated by the
stemic use of 5-fluorouracil (5 g/course), cyclophos-
amide (5 g/course), and mitomycin C (50 mg/course).
diation therapy, including radium implants, is indi-
ted in pelvic recurrences, and a moderately aggressive
urse should be followed if the patient can follow it.
operation was curative in 15.5% of the cases, and
.5% of those undergoing reoperation remained in
od condition. The age-adjusted 5-yr survival rate
s 7% in patients with recurrent colorectal carci-
ma.

75 ENZYMATIC STUDIES OF NORMAL AND MALIGNANT INTESTINAL EPITHELIUM. *(E.)* Salser, J.
; Balis, M. E. (Sloane-Kettering Inst. Cancer Res.,
York, N.Y.). *Cancer* 34(3):889-895, 1974.

evious studies have suggested that DNA synthesis
d thymidine kinase activity are increased in precancerous cells and that tumor cells of the colon are under controls that more closely resemble those in crypt than in surface cells. To further investigate this, thymidine kinase activity was studied in extracts from tumors and adjacent normal gastrointestinal mucosa obtained from surgical specimens. Thymidine kinase activity was present in 2 forms: one soluble and one particulate-associated. Both forms were activated by phospholipase C. Most of the soluble activity was in the dividing cells of the crypts. Nondividing surface cells were stimulated more by phospholipase C than were crypt cells. Tumor cells, but not fetal tissue, had greater thymidine kinase activity than normal mucosa. Thymidine kinase activity of tumors of the stomach, ileum, and cecum were not increased by phospholipase C, whereas normal tissue thymidine kinase activity was stimulated 2.5-fold. Fetal thymidine kinase was increased 7 to 10-fold by phospholipase C, a finding in contrast to previous reports. Heat inactivation studies and studies of the effects of mercaptans and glutathione on thymidine kinase activity suggest that thymidine kinase in tumors differs from that in normal colon.

6976 CHANGES IN COMPOSITION OF MUCIN IN THE MUCOSA ADJACENT TO CARCINOMA OF THE COLON AS COMPARED WITH THE NORMAL: A BIOCHEMICAL INVESTIGATION. *(E.)* Filipe, M. I.; Cooke, K. B. (Westminster Med. Sch., London, England). *J. Clin. Path.* 27(4):315-318, 1974.

In patients with carcinoma of the large intestine, samples of normal mucosa distant from the tumor as well as specimens from mucosa immediately adjacent to the tumor (transitional mucosa) were analyzed for protein, hexosamine, and sialic acid levels. The ratios of protein/wet weight of tissue were constant in the mucosa from both areas. However, a highly significant increase of hexosamine values, measured as glucosamine HCl, was seen in transitional mucosa (1.90 μg/mg wet tissue) compared with normal mucosa (1.38). A similar significant difference was found between sialic acid content of transitional mucosa (1.31) and that of normal mucosa (0.78 μg/mg wet weight of tissue). The results suggest that the epithelial cells of the transitional mucosa may be of the immature type on the basis of increased hexosamine levels and also higher percentage of neuraminidase-sensitive sialic acids. The overall picture of these cells producing mainly sialomucus rather than sulfated material is similar to the pattern of goblet cells in early fetal life. Available data do not permit certain conclusions as to whether that comparison is a true one and if so, what factors are responsible for regression to an embryonic type of cell activity.

6977 MULTIPLE CARCINOMAS OF THE COLON AND RECTUM.

(E.) Ekelund, G.R.; Pihl, B. (Malmo Gen. Hosp., Sweden). *Cancer* 33(6):1630-1634, 1974.

Of 960 patients with colorectal carcinoma seen over a 10-yr period, 44 (4.6%) had multiple synchronous carcinomas and 22 (2.3%) had metachronous carcinomas. The group with synchronous carcinomas consisted of 28 men and 16 women with a mean age of 68 yr; 7 of these patients had 3 lesions and 37 had 2. Of the total of 95 carcinomas, 55% were located in the rectum and sigmoid colon. At least 1 adenomatous or adenovillous polyp was found in 24 (54.6%) of the 44 patients with synchronous carcinomas. Surgery was performed on 29 of these patients and a palliative procedure on 13. In this group, the corrected 5- and 10-yr survival rate was about 41%, while the crude 10-yr survival was 24%. These rates did not differ significantly from those of the parent series. Of the 22 cases of metachronous carcinomas, 14 were previous to and 8 subsequent to surgery. The average interval between detection of the 1st and 2nd lesions was 104 months, and in 6 cases the 2nd lesion was found only at autopsy. Nine of the remaining 16 patients were men and 7 were women with a mean age of 70 yr at time of discovery of the 2nd lesion. Six of the 16 patients had adenomatous or adenovillous polyps, while 1 had a submucous lipoma. The corrected 5- and 10-yr survival rates after treatment of the 2nd lesion were 51.3% and 30.7% resp.; the corresponding crude figures were 37.5% and 15.0%. In this population, the average annual incidence of multiple primary colorectal carcinoma was 2.6/100,000 inhabitants. The results indicate that every case of colorectal carcinoma requires a thorough preoperative examination of the large intestine. Patients undergoing surgery for cure should be regularly followed up for the rest of their lives for metachronous carcinomas. Therefore, figures on the frequency of metachronous carcinomas are regarded as provisional.

6978 STUDIES OF MITOTIC ACTIVITY OF ADENOCARCINOMATOUS CELLS IN THE RECTUM.

(E.) Kalcheva, V.; Tileva, M. D. (Med. Acad. Fac. Med., Plovdiv, Bulgaria). *J. Abdom. Surg.* 16(6):160-161, 1974.

The mitotic activity of adenocarcinoma cells in the rectum was studied in 34 biopsy specimens. Morphologically, all 24 graded adenocarcinomas belonged to grades II or III and mitotic activity was almost ide tical for cells of both grades. The mean mitotic index was 19.9/1000 cells for grade II and 22.6/1000 cells for grade III, while the range of the index was 7.3-36.5/1000 cells for the two grades. The difference in mitotic activity between grade II and III cells and that of normal intestinal crypt cells was statistically significant. In 10 gelatinous adenocarcinomas, mitotic activity was low (mean, 5.0/1000 cells) and did not differ significantly from that of normal cells. Analysis of clinical data indicated that, regardless of differentiation grade, the mitot index of cancer lesions localized in the bowel was almost twice that of neoplastic cells invading surrounding tissue and involving lymph nodes.

6979 GOBLET CELL CARCINOID OF THE APPENDIX.

(E.) Subbuswamy, S. G.; Gibbs, N. M.; Ross, C. F.; Morson, B. C. (St. Mark's Hosp., London, England). *Cancer* 34(2):338-344, 1974.

Tumorous appendix tissue removed at appendectomy from 7 men and 5 women (aged 21-69 yr) was examined to identify the neoplasms. All but 2 of the 12 tumors were microscopic. Diffuse involvement of the whole appendix was found in only 1 case, whereas th tumors were at the proximal part in 4 patients, at the distal half in 4, and at the tip in 3. Histologically, the tumors differed from both ordinary carcinoid and adenocarcinoma in that the principal cell type closely resembled normal goblet cells of intestinal epithelium. These cells contained distinct mucin globules which were predominantly acid. In addition, argentaffin and Paneth's cells were present in considerable numbers in some tumors. In all cases, continuity of submucosal tumor cells wit basiglandular cells in the mucous membrane crypts was observed. A kinship with carcinoid was suggested by the basiglandular position of the tumor, its well-differentiated character, and good prognosis after simple appendectomy. However, the histology is sufficiently different to warrant separate classification as a goblet cell carcinoid. Of the 9 pa tients treated by simple appendectomy, 6 are well 2-5 yr after the operation; 1 was lost to followup, 1 died from coronary thrombosis, and 1 died from carcinoma of the stomach. Of the 3 patients who un derwent appendectomy followed by right hemicolectomy, 1 is well after 6 yr, 1 developed primary carci noma of the prostrate after 2 yr, and 1 developed bilateral ovarian tumors and peritoneal metastases after 5 yr. In the last case, the histology was al most identical to that of the primary tumor of the appendix.

6980 INDUCTION OF COLONIC CANCER IN THE RAT BY A SINGLE INJECTION OF 1,2-DIMETHYLHYDRAZI

(Fr.) Martin, M. S.; Martin, F.; Justrabo, E.; Knopf, J. F.; Bastien, H.; Knobel, S. (Lab. Exp. Me Immunol., Fac. Med., Dijon, France). *Biol. Gastroenterol. (Paris)* 7(1):37-42, 1974.

Consanguineous BD IX rats, bred by mating brothers with sisters, were injected with 1,2-dimethylhydraz (40 mg/kg s.c.) at ages 1, 10, and 30 days. Of the

rats treated, 11 developed carcinomas of the
on, 5 colonic dysplasia, and 6 colonic hyperplasia.
the 11 colonic carcinomas, 1 developed in a rat
ected at age 1 day, 3 in rats injected at age 10
s, and 7 in rats injected at age 30 days. The
reasing incidence of carcinomas with age may re-
t from the fact that microsomal hydroxylase, which
verts dimethylhydrazine into azoxymethane and then
o methylazoxymethanol, is present at birth but
y reaches maximum levels at age 30 days. The
n survival time for rats with colonic cancer was
days and ranged from 600 days for those treated
ages 1 and 10 days to 420 days for those treated
age 30 days. Most of the tumors were highly dif-
entiated adenocarcinomas, but some were atypical
us-secreting carcinomas. No metastases, such as
se which occurred previously in rats injected re-
tedly with 1,2-dimethylhydrazine, were found. Ex-
intestinal lesions included gastric glandular hy-
plasia (7 cases); 1 adenoma and 1 cavernous heman-
ma of the liver; 1 fibrosarcoma and 1 dysgenetic
or of the kidney; and 1 salivary gland adenoma.
tic dilatation of the biliary tract and granular
enerative lesions of the liver were also relatively
mon. These findings suggest that colonic cancer
result from a single exposure to a carcinogen in
ldhood or adolescence and point up the difficul-
s encountered in etiological investigations of in-
tinal carcinomas in humans.

1 PHYSIOLOGICAL STUDIES ON THE LARGE INTES-
TINE OF MICE WITH HEREDITARY MEGACOLON AND
ENCE OF ENTERIC GANGLION CELLS. *(E.)* Wood, J.
(Univ. Kansas Med. Ctr., Kansas City). *Proc. Int.*
p. Gastrointest. Motility, 4th, 1973, pp. 177-187.

electrical and mechanical activity of the large
estine was studied in piebald mice and their nor-
siblings. Piebald mice carry a recessive gene
ch reduces the number of ganglion cells of the
tal colon and rectum and produces megacolon simi-
to Hirschsprung's disease. Electrical slow
es and action potentials occurred in the large in-
tines of both normal and abnormal mice. The prin-
al difference between normal mice and their abnor-
siblings was increased incidence of discharge of
ion potentials associated with uncoordinated pha-
contractions superimposed upon tonic contracture
the circular muscle layer of the distal aganglion-
segment in the abnormal mouse. The distended colon
the abnormal mouse and the entire length of the nor-
bowel showed bursts of action potentials which ac-
npanied peristaltic waves of circular muscle contrac-
on. During propulsive motility in the rectum, ac-
vation of the circular muscle was preceded by coor-
nated contraction of the longitudinal muscle only in
normal bowel. These findings suggest that inherent
ction of the muscularis externa is not impaired in
e with megacolon. Abnormal motor activity of the
nglionic segment *in vitro* appears to result entirely
om the absence of regulation and coordination of
musculature by enteric ganglion cells. Neuronal
ckade with 2.25 x 10^{-5} g/ml lidocaine produced in
distended region of the abnormal colon and along
entire length of the normal colon an increase in
ike activity and uncoordinated contractile activity
ich resembled the electrical and mechanical activity
the aganglionic segment in the absence of drugs.

6982 INTERNAL ANAL SPHINCTER DERANGEMENT WITH ANAL FISSURES. *(E.)* Nothmann, B. J.; Schuster, M. M. (Baltimore City Hosp., Md.). *Gastroenterology* 67(2):216-220, 1974.

Manometric studies were performed on the internal and external anal sphincters on 7 patients with confirmed anal fissures, 7 patients with irritable bowel syndrome, and 10 normal controls. In patients with irritable bowel syndrome and in the control group, rectal distension with 50 ml of air caused an abrupt relaxation of the internal sphincter lasting for an average of 15 sec and a brief rapid contraction of the external sphincter which coincided with relaxation of the internal sphincter. Relaxation of the internal sphincter also occurred in patients with anal fissures, but this was followed by a marked and often prolonged contraction above the initial base line. Although this overshoot phenomenon sometimes occurred in controls and patients with irritable bowel syndrome, (1) resting pressure in the internal sphincter balloon was higher in patients with fissures; (2) the overshoot pattern occurred in 90% of suprathreshold distensions performed on patients with fissures and in only 26% of other subjects; (3) amplitude of the overshoot contraction was higher in patients with fissures; and (4) the threshold for stimulation of overshoot was lower in patients with fissures. The overshoot phenomenon was no longer observed, and reflex responses had returned to normal in all 3 patients studied after successful treatment of fissures. Administration of diazepam (10 mg i.v.) to a patient with anal fissures completely abolished the external sphincter response, while the internal sphincter response remained unchanged and continued to demonstrate the overshoot pattern. Overshoot was also observed in a patient who, in addition to an anal fissure, had a spinal cord lesion which resulted in complete paralysis of the external anal sphincter. These findings suggest that the external anal sphincter is not significantly involved in the pathophysiology of anal fissures. A reflexly stimulated internal sphincter spasm, which may occur when stool enters the rectum or during defecation, appears to be more important. Therefore, surgical approaches should be directed to the internal, rather than to the external, anal sphincter.

6983 REMOVAL OF POLYPS OF COLONOSCOPY. *(Fr.)* Bognel, J. C.; Liguory, A.; Bitoun, A.; Duhamel, J. (St. Antoine Hosp., Paris, France). *Vie Med. (Paris)* 54(36):4615-4616, 4625-4626, 1973.

By using an A.C.M.I. fiber colonoscope attached to a diathermy loop, 30 colonic polyps were removed from 26 patients. Although polyps can be removed on an outpatient basis, it is recommended that patients be hospitalized if they are in poor condition, if intensive premedication is necessary, or if surgery presents any difficulties. Under ideal conditions, the head of the polyp should not measure more than 2 cm, it should have a straight stalk at least 1 cm long, and it should be located in a straight, wide part of the colon. After mechanical coagulation, the polyps were coagulated by brief and repeated passage of current through them. Polyps were then extracted and subjected to histological examination. Of the 30 polyps removed, 3 were inflammatory, 22 were benign, 1 was degenerated, and 4 were malignant. Secondary surgical resections were performed on most of the malignant polyps. An 80-yr-old patient who had 3 polyps, including a large malignant sessile polyp, developed pelvic peritonitis 24 hr after endoscopy. Laparotomy and resection could not be performed in this case because the patient had hypertension and had suffered a recent myocardial infarction. Although the peritonitis responded to massive doses of antibiotics, the patient died suddenly of an embolism 15 days after endoscopic removal of the polyps. Another patient developed acute pneumoperitoneum shortly after colonoscopy but responded to exsufflation with a needle. None of these patients bled.

6984 ABNORMAL PATTERNS OF MUCUS SECRETION IN APPARENTLY NORMAL MUCOSA OF LARGE INTESTINE WITH CARCINOMA. *(E.)* Filipe, M. I.; Branfoot, A. C. (Westminster Med. Sch., London, England). *Cancer* 34(2):282-290, 1974

LARGE INTESTINE

Ulcerative Colitis

04 DIFFERENTIAL DIAGNOSIS OF ULCERATIVE AND GRANULOMATOUS COLITIS BY SIGMOIDOSCOPY,
CTAL BIOPSY AND CELL COUNTS OF RECTAL MUCOSA. *(E.)*
relitz, B. I.; Sommers, S. C. (Mt. Sinai Sch. Med.,
w York, N.Y.). *Am. J. Gastroenterol.* 61(6):460-
9, 1974.

er a 5 yr period, 365 patients with inflammatory
wel disease were classified into 7 categories on
e basis of radiological findings supplemented by
story and clinical data: ulcerative colitis, sig-
oidoscopy positive (155); sigmoidoscopy negative
2); granulomatous colitis or ileocolitis, sigmoi-
oscopy positive (44); sigmoidoscopy negative (54);
eitis or jejunitis (13); colitis type undetermined
5); and possible colitis (12). The histopatholo-
c features of sigmoidoscopically positive ulcera-
ve and granulomatous colitis demonstrated no sig-
ficant differences. Therefore, differentiation
ould rely on clinical, radiologic, and sigmoido-
copic results unless a granuloma is found. Cell
unts of sigmoidoscopically positive ulcerative
litis showed significantly more pyknotic epithe-
al cells, while lamina propria connective tissue
lls demonstrated no significant differences between
cerative and granulomatous types. In the ulcera-
ve type of colitis with negative sigmoidoscopy,
ere were significantly more mast cells, plasma
lls, eosinophils and neutrophils in connective
ssue cell counts, but more macrophages in the
anulomatous type. In general, when sigmoidoscopic
pearance is normal (i.e., negative) or becomes so
ter inflammation subsides, connective tissue cell
unts have shown significant differences useful to
stinguish ulcerative from granulomatous colitis.
ed together with rectal examinations, the combina-
on of gross sigmoidoscopic appearance and cell
unts of rectal biopsies appears to provide the best
fferential diagnostic criteria.

05 ULCERATIVE COLITIS IN PREGNANCY. *(E.)*
McEwan, H. P. (Roy. Maternity Hosp., Glas-
w, Scotland). *Med. Chir. Dig.* 2(6):355-358, 1973.

e effects of ulcerative colitis on pregnancy and
ce versa were examined in 38 medically treated
men with 50 pregnancies, 9 women undergoing surgery antenatally or immediately postpartum, and 11 pregnant women with surgical treatment of the disease previous to pregnancy. In the 38 medically treated women, no neonatal deaths, maternal deaths, or fetal abnormalities occurred. Mode of delivery was abortion in 5 cases (4 spontaneous and 1 therapeutic), 41 vaginal deliveries (1 stillbirth), and 4 cesarean sections. In general, the outcome of pregnancies was good; but if the colitis was severe, the pregnancy was endangered and abortion a possibility. On the other hand, the course of mild or inactive ulcerative colitis was not greatly influenced by pregnancy. Surgery during pregnancy in 9 cases showed a poor outcome with only 5 live births and with 3 maternal deaths, 2 during pregnancy and 1 *in puerperium*. Twelve pregnancies in 11 patients after surgery prior to pregnancy were terminated by 9 vaginal deliveries and 3 cesarean sections (with 1 maternal death due to unrelated causes), all with successful fetal outcome. Results indicate that ulcerative colitis in its mild form or in the inactive phase does not contraindicate pregnancy. If active, avoidance of pregnancy is desirable since surgical treatment is associated with a high maternal death rate and infant loss.

7006 ULCERATIVE COLITIS AND ENTEROCOCCI. *(E.)*
Van der Wiel-Korstanje, J. A. A. (Microbiol. Lab., State Univ., Utrecht, Netherlands). *Antonie van Leeuwenhoek* 40(2):325, 1974.

In 13 patients with ulcerative colitis and in 25 normal subjects of comparable age, the number of enterococci/g feces was counted regularly for several weeks or months. All isolated strains belonged to the serological group D and could be identified biochemically as *Streptococcus faecalis*, *S. faecium*, *S. bovis*, *S. mobilis*, and the so-called Q streptococci. In normal subjects, the number of enterococci varied between 10^5 and 10^7/g feces, with generally only 1 or 2 species present in each sample; *S. mobilis* was never found. In patients with ulcerative colitis, the number of enterococci ranged between 10^7 and 10^9/g feces; the number of species/sample was higher; and *S. mobilis* occurred frequently. About 50% of the strains of *S. faecalis*, *S. faecium*, and Q streptococci produced a mucinase, compared with 85% of the *S. mobilis* strains.

Most of the strains from patients produced a hyaluronidase. Some strains formed lactic acid from mucin, hyaluronic acid, N-acetylneuraminic acid, and N-acetylglucosamine. It is theorized that the large amount of mucus in diseased bowels stimulates the growth of enterococci, especially *S. mobilis*, and that hyaluronic acid released from the ulcerations is another growth-promoting factor. The lactic acid in the feces of ulcerative colitis patients is apparently related to the 100-fold increase of enterococci and for the most part may be considered as the metabolic end product of mucus breakdown.

7007 MITIGATION OF EXPERIMENTAL INFLAMMATORY BOWEL DISEASE IN GUINEA PIGS BY SELECTIVE ELIMINATION OF THE AEROBIC GRAM-NEGATIVE INTESTINAL MICROFLORA. *(E.)* Van der Waaij, D.; Cohen, B. J.; Anver, M. R. (Animal Res. Facility, Univ. Michigan, Ann Arbor). *Gastroenterology* 67(3):460-472, 1974.

The effect of selective elimination of the aerobic gram-negative intestinal flora on the development of experimental bowel disease was studied in male English short-hair albino guinea pigs. Lesions were induced with 2 or 5% degraded carrageenan administered in the drinking water for 30 to 44 days. Craterous cecal or colonic ulcers, crypt abscesses, mucosal distortion, mesenteric lymphadenopathy, marked cecal or colonic lymphoid hyperplasia, and other lesions were seen in conventional guinea pigs treated with degraded carrageenan. Other guinea pigs that were treated with 2% degraded carrageenan, but freed of Enterobacteriaceae species by the administration of trimethoprim with sulfamethoxazole, and subsequently maintained in isolators, exhibited virtually no lesions. Enterobacteriaceae-free animals that were treated with 5% degraded carrageenan had significantly fewer lesions than were observed in the conventional degraded carrageenan-treated animals. Biotyping of bacterial isolates indicated that Enterobacteriaceae species generally, and not a single biotype, were associated with the lesions. The bacteria presumably stimulated an immunological response after penetration of the intestinal mucosal barrier. Thus, inflammatory bowel disease in guinea pigs, induced with degraded carrageenan, may provide a useful model for investigating immunological aspects of human inflammatory bowel disease.

7008 TITRE OF ANTI-E. coli ANTIBODIES IN ULCERATIVE COLITIS. *(E.)* Kovacs, A. (Semmelweis Univ. Med. Sch., Budapest, Hungary). *Digestion* 10(3):205-209, 1974.

The antibody titers against *Escherichia coli* 0:14 were determined with an hemagglutination method in the serum of 65 patients with ulcerative colitis, of 20 patients with other intestinal diseases, and of 35 patients with diseases of other organ systems. High antibody titers, found in 3 patients with active ulcerative colitis, decreased when the patients became asymptomatic. No significant difference was observed between the groups of patients. These results, which contradict previously published data, do not support the view that *E. coli* plays an important role in the pathogenesis of ulcerative colitis.

7009 ULCERATIVE DISEASE OF THE COLON IN LABORATORY ANIMALS INDUCED BY PEPSIN INHIBITORS. *(E.)* Marcus, R.; Watt, J. (Clatterbridge Hosp., Bebington, England). *Gastroenterology* 67(3):473-483, 1974.

The administration of pepsin inhibitors, sodium lignosulfonate, or sulfated amylopectin in low concentration (1%) in the drinking fluid to guinea pigs and rabbits over a 2 to 6 week period caused ulcerative disease of the colon in 50-100% of the animals. These doses are comparable to therapeutic doses used clinically. The clinical and morphological features were very similar to ulcerative disease of the colon induced by carrageenan. Animals had diarrhea which varied in severity; occult or, in some cases, visible blood in the feces; and either weight loss or failure to gain weight. Morphological features included multiple focal ulceration in the cecal mucosa with extension distally into the colon and rectum; focal cellular aggregates, including macrophages, in the mucosa; cystic dilatation of the mucosal glands; and crypt abscesses. Careful toxicity tests and evaluation of the potential hazards of pepsin inhibitors are necessary before releasing such preparations for therapeutic use.

7010 "PRECANCER" LESIONS IN ULCERATIVE COLITIS: A RETROSPECTIVE STUDY OF RECTAL BIOPSY AND COLECTOMY SPECIMENS. *(E.)* Yardley, J. H.; Keren, D. F. (Johns Hopkins Hosp., Baltimore, Md.). *Cancer* 34(3)suppl.:835-844, 1974.

To further define and determine the occurrence of precancerous lesions in patients with ulcerative colitis, 41 colectomy specimens and 412 rectal biopsies from 204 patients with ulcerative colitis were studied. Seven of 8 resected specimens containing carcinomas also showed flat or adenomatous mucosal lesions, characterized by the marked epithelial atypia, villous change, and reduced epithelial mucus content indicative of precancer. Similar precancerous changes were found in 3 of the 412 rectal biopsies studied: 2 of these patients had subsequent colectomy with invasive carcinoma. Diffuse precancerous changes throughout the colon in the form of multiple adenomas were found in the 3rd patient. It is concluded that precancerous changes are valid means for identifying the population of ulcerative colitis patients who have the highest risk of developing colonic carcinoma and that some of these individuals can be detected by examining rectal biopsies. However, active colitis artificially increased the number of biopsies showing changes suspicious of precancer, and precancer involving other parts of the colon can go undetected if only rectal biopsies are examined. The latter patients might be more successfully identified by using a combination of colonoscopy and biopsy at regular intervals.

RECTAL BIOPSY AND PRECANCER IN ULCERATIVE
COLITIS. *(E.)* Myrvold, H. E.; Kock, N.
hren, C. (Sahlgren Hosp., Univ. Goteborg, Swe-
Gut 15(4):301-304, 1974.

l biopsies and colectomy specimens were obtain-
om 47 ulcerative colitis patients with involve-
of the entire large intestine. They underwent
ive proctocolectomy and were investigated for
rence of reactive cellular atypia and precancer-
hanges. In 24 patients no precancer or cellular
a was found in rectal biopsies, but operative
mens showed cellular atypia in 9 and precancer-
hanges in 1. Of 16 patients with cellular atypia
ctal biopsy, 10 had precancer in operative spec-
. In only 7 patients was precancer found in both
l biopsies and operative specimens; 5 of the 7
had carcinoma. In operative specimens the whole
s membrane showed precancerous changes in 2 cases
atchy distribution of the lesion in the rest.
atients with no precancer in the rectum of oper-
specimens had precancer at other sites in the
. Precancer and carcinoma were found, resp., in
nd 6% of 35 operative specimens from patients
ulcerative colitis for less than 10 yr. The fact
precancer is in most cases patchy and in some
does not involve the rectum limits the useful-
of rectal biopsy in patients with ulcerative
tis. However, biopsies can be of value in select-
atients for operation. Thus in all 7 patients
precancer in the rectal biopsy, precancer or pre-
r associated with carcinoma was found in the col-
y specimen. The results also indicate that pa-
s with a short history of ulcerative colitis are
at risk of developing carcinoma than has been
ed.

TISSUE CYTOGENETIC STUDIES IN CHRONIC ULCER-
ATIVE COLITIS AND CARCINOMA OF THE COLON.
Xavier, R. G.; Prolla, J. C.; Bemvenuti, G. A.;
ner, J. B. (Dept. Med., Univ. Chicago, Ill.).
r 34(3):684-695, 1974.

genetic studies were conducted on rectal mucosal
from patients with Crohn's disease, ulcerative
tis, and colonic carcinoma. Cytogenetic prepara-
were obtained by brushing the rectal mucosa
g proctoscopy. Of 61 individuals examined, 33
ided reliable material for chromosomal analysis:
rmal controls, 5 with Crohn's disease involving
colon, 10 with chronic ulcerative colitis, 4
ulcerative colitis complicated by cancer of the
in whom special care was taken to obtain separ-
samples from both colitic and cancerous tissue,
with cancer of the colon alone. Chromosome
and karyotypes were normal in all controls and
ents with Crohn's disease. In chronic ulcera-
colitis the modal chromosome number remained
e diploid range, but aneuploid, or possibly
en polyploid cells were seen in 2 patients, and
e inflamed mucosa of 2 other patients with can-
of the colon associated with ulcerative colitis.
these cells were in the hypotetraploid range.
hromatid breaks were found in the controls and
atients with Crohn's disease, but patients with
rative colitis and colon cancer demonstrated a
variable number of breaks. Profound abnormalities were detected in patients with carcinoma: aneuploidy, chromatid breaks, and marker chromosomes.

7020 ELECTRON MICROSCOPY OF SMALL INTESTINAL MUCOSA IN PANCREATIC INSUFFICIENCY. *(E.)* Shimoda, S. S.; Saunders, D. R.; Schuffler, M. D.; Leinbach, G. L. (Dept. Med., Univ. Washington, Seattle). *Gastroenterology* 67(1):19-27, 1974.

Fat absorption was investigated in 4 patients with pancreatic insufficiency. Jejunal contents were analyzed chemically, and jejunal mucosal biopsies were studied with an electron microscope after intragastric infusion of test meals over 15 min. Lipolytic activity was low in postprandial jejunal contents; lipolysis of the test meal was reduced, but 2 mM free fatty acid was solubilized in the aqueous phase of intestinal contents. In spite of these appreciable quantities of solubilized free fatty acids, no evidence of fat absorption was detected morphologically. Electron microscope study revealed that essentially no visible fat particles entered or left the jejunal absorptive cells for up to 2 hr after a fatty meal. Lipolysis, and the number of fat droplets in absorptive cells, could be normalized by adding 5 g of pancreatic enzymes to the test meal, indicating that there was no intrinsic mucosal defect. Fat absorption was also morphologically normal after feeding a predigested meal whose enzymes were inactivated, suggesting that pancreatic enzymes did not play a major role in enhancing absorption of solubilized free fatty acid. Lipolysis was low and mucosal fat droplets were absent in the proximal ileum, indicating that digestion and absorption of the test meal were not occurring in the distal small intestine. Despite absent morphological evidence of fat absorption, patients absorbed 30 to 70% of their dietary fat. It is possible that in pancreatic insufficiency, fatty acids enter and leave the absorptive cells as monomers, or as small aggregates which are not detected by present electron microscopic techniques.

7021 NEW ONCOFETAL ANTIGEN FOR HUMAN PANCREAS. *(E.)* Banwo, O.; Versey, J.; Hobbs, J. R. (Westminster Hosp. Med. Sch., London, England). *Lancet* 1(7859):643-645, 1974.

In a search for fetal pancreas proteins that can specifically identify neoplasm of the pancreas and that are not present in adult pancreas but are found in the blood of patients with pancreatic tumors, antisera against stabilized homogenates of whole human fetal pancreas were raised in rabbits and absorbed with normal adult pancreas and albumin. By 2-dimensional immunoelectrophoresis in agarose containing antiproteases, a characteristic peak was shown in sera from 36 of 37 patients with carcinoma of the pancreas. It was also found against extracts of fetal pancreas or adult pancreatic carcinoma. It was absent from sera of 38 other patients, including those with gut cancers (8 positive for colonic carcinoembryonic antigen); hepatoma (2 positive for α-fetoprotein); other causes of jaundice (11); and acute (5) or chronic (12) pancreatitis. It was absent in extracts of fetal colon and fetal liver. Thus far the adsorbed antisera seem to detect an oncofetal antigen complex specific to pancreas since it has been identified only in fetal pancreas or in adult pancreatic carcinoma, and is distinct from th 3 known occofetal antigens. Until it has been isolated and purified, and until a radioimmunoassay ha been established, the full extent of its applicability remains unknown.

7022 FAMILIAL HYPERLIPOPROTEINAEMIA AND THE EXOCRINE PANCREAS. *(E.)* Herfort, K.; Sobra, J.; Heyrovsky, A. (Fac. Gen. Med., Charles Univ., Prague, Czechoslovakia). *Rev. Czech. Med.* 19(4):230-237, 1973.

Of 37 patients (16 men and 20 women; mean age, 40. yr) with familial hyperlipoproteinemia, 17 (45.9%) experienced attacks of epigastric pain of pancreati origin. The pain was spastic, usually very intense and generally persisted for several days. Accordin to Frederickson's classification, these patients ha types I, IV, and V familial hyperlipoproteinemia. The pain did not occur in type II or III patients. Exocrine pancreatic secretion was impaired in 27 patients (72.9%), including 17 who had attacks of epigastric pain and 10 who did not. The most frequent finding was a reduced lipase output (70.2%), followed by a reduction of the bicarbonate output (62.1%) maximum bicarbonate concentration (59.5%), and volu (37.8%). Amylase output was reduced in only 29.7%. Three or more parameters of pancreatic secretion we reduced in the 2 patients with type I, in 8 of 17 with type IV, and in 5 of 9 with type V hyperlipopr teinemia. None of the patients with types II and I had 3 or more abnormalities in parameters for pancr atic exocrine secretion. It is possible that lipid abnormalities characteristic of types I, IV, and V familial hyperlipoproteinemia are only one manifest tion of the inborn defect in lipid metabolism. Sin there is no evidence that these lipid abnormalities alone cause changes in the exocrine pancreas, anoth manifestation could be a defect in the enzyme makeu of acinar cells which results in the clinical symptoms and functional changes observed in these patients. Impaired pancreatic secretion in asymptomatic patients with familial hyperlipoproteinemia suggests that lipoprotein abnormalities precede and ma participate in the development of impaired pancreat function, e.g. acute or chronic pancreatitis.

32 ACUTE HEMORRHAGIC PANCREATITIS AND PSEUDOCYST DUE TO MUMPS. *(E.)* Feldstein, J. D.;
hnson, F. R.; Kallick, C. A.; Doolas, A. (Rush Pres-
terian St. Luke's Med. Ctr., Chicago, Ill.). *Ann.*
rg. 180(1):85-88, 1974.

mps hemorrhagic pancreatitis was documented in a 4-
old boy with a history of exposure to mumps paroti-
is. Signs and symptoms at admission included shock,
igastric pain, and slight bilateral parotid swelling.
ver the next 36 hr, the abdomen became more tender
nd distended. A flat plate of the abdomen revealed
sentinel loop of distended bowel and a diffuse hazi-
ess. Rectal temperature rose to 39.5 C. Serum amyl-
se was 680-816 U and an abdominal tap revealed san-
uinous fluid with 7600 U amylase. Abdominal surgery
evealed a necrotic, hemorrhagic, and grossly edematous pancreas; the omentum and mesentery exhibited
iffuse areas of saponification, necrosis, and hemor-
hage. A total of 2000 ml of serosanguinous fluid
as drained. After the patient pulled out his drains
days later, re-exploration showed a large pancreatic
seudocyst which was drained into a jejunal Roux-en-y
oop. Recovery was uneventful. During 4 weeks test-
ng, mumps titers showed a 4-fold increase in virus
iters, indicative of recent mumps infection. When
urgery is indicated for hemorrhagic pancreatitis,
rainage of the lesser sac usually prevents pseudo-
yst formation; if a pseudocyst does occur, drainage
s required to eliminate disabling pain and chronic
ancreatitis. Live attenuated mumps vaccine, now
vailable for immunizing school age children, may
liminate this source of pancreatitis.

7033 CHARACTERIZATION OF AN ADDITIONAL PROTEIN IN PANCREATIC JUICE OF MEN WITH CHRONIC CALCIFYING PANCREATITIS: IDENTIFICATION TO LACTOFERRIN. *(E.)* Colomb, E.; Estevenon, J. P.; Figarella, C.; Guy, O.; Sarles, H. (Unit Res. Dig. Pathol., INSERM, Marseille, France). *Biochem. Biophys. Acta.* 342(2):306-312, 1974.

The protein composition of normal pancreatic juice and pancreatic juice from men with chronic calcifying pancreatitis was compared using immunological techniques. An additional protein, missing in normal pancreatic juice, was demonstrated in 6 pathological pancreatic juice samples assayed against antiserum treated with soluble antigens to precipitate antigen-antibody complexes. This protein was weakly anionic at pH 8.6, had a molecular weight close to 69,000, and was immunologically identical to lactoferrin, an iron-binding protein present in various external secretions. Lactoferrin concentration in pancreatic juice, determined in 10 patients with chronic calcifying pancreatitis, was very low (0.03-0.34% of total proteins). No relation was found between alkaline phosphatase activity and lactoferrin presence in pathological pancreas juices. Therefore, lactoferrin in pancreatic juice is probably not due to a leukocyte contamination but is a component of the pancreatic secretion. As lactoferrin was present in normal serum at a very low level, it is hypothesized that lactoferrin in pathological pancreatic juice could result from selective transport of the protein from serum to pancreatic juice.

LIVER AND BILIARY TRACT

7050 ^{67}GALLIUM SCANNING IN THE DIAGNOSIS OF LIVER DISEASE. *(E.)* James, O.; Wood, E. J.; Sherlock, S. (Roy. Free Hosp., London, England). *Gut* 15(5):404-410, 1974.

^{67}Gallium (^{67}Ga) citrate liver scans were made on 60 selected patients following a scan with a radioactiv colloid preparation. The ^{67}Ga scan correctly identified the site of primary liver carcinoma in 14 of 16 patients, including 9 of 10 patients in whom the carcinoma developed in a cirrhotic liver. In contrast, a colloid scan positively identified the site

only 4 of these 10 cirrhotic subjects. The α_1-
etoprotein test was positive in 8 of the 16 patients,
ncluding the 2 in whom the ^{67}Ga scan was negative.
positive ^{67}Ga scans were seen in 15 patients with
rrhosis in whom a space-occupying lesion could not
ruled out on the basis of a colloid scan. ^{67}Ga
trate scanning appears to be the most reliable
echnique available for diagnosing primary liver cell
ancer. Uptake of ^{67}Ga in secondary metastatic tu-
ors within the liver was less frequent, and this
ethod appears to have much less value in the detec-
ion of these metastases and of bile duct carcinoma
han of primary liver cell carcinoma. The ^{67}Ga scan
as positive in 6 out of 6 patients with pyogenic
bscess either in the liver or adjacent to it. In
of these patients a preceding colloid scan had
hown no definite filling defect in the liver. In
iew of the low incidence of false positive scans
nd of false negative results in selected patients,
Ga scanning is a valuable additional tool in the
iagnosis of liver disease.

051 GAMMA-GLUTAMYL-TRANSPEPTIDASE IN HEPATO-
BILIARY DISEASE. VALUE AS AN ENZYMATIC
IVER FUNCTION TEST. *(E.)* Cuschieri, A.; Baker, P.
. (Dept. Surg., Univ. Liverpool, England). *Br. J.*
cp. Pathol. 55(2):110-115, 1974.

e diagnostic and prognostic value of serum γ-
lutamyl-transpeptidase activity in hepatobiliary
isease was investigated in 52 patients, including
5 with alcoholic cirrhosis, 13 with cryptogenic
irrhosis, 6 with chronic active hepatitis, 12 with
xtrahepatic bile duct obstruction, 3 with primary
epatic neoplasm, and 2 with primary biliary cir-
hosis. Mean enzyme activity in the 29 cirrhotics
53.8 mU/ml) was significantly higher than in the
3 controls with normal liver function tests (14.8
U/ml). There was no significant difference between
lcoholic and cryptogenic cirrhosis. However, clas-
ification of all cirrhotic patients according to
egree of disease indicated that enzyme level de-
lined significantly with progress of the disease,
eaching very low values in terminal hepatic coma.
n the cirrhotic group as a whole, serum γ-glutamyl-
ranspeptidase activity was significantly correlated
ith serum albumin level. Enzyme activity was ele-
ated (240.6 mU/ml) in chronic active hepatitis, and
here was no significant difference in values during
elapse and remission. In biliary tract obstruction,
he serum γ-glutamyl-transpeptidase activity remained
levated (156.0 mU/ml) for up to 4-6 weeks after sur-
ery. Persistently high serum enzyme values (in ex-
ess of 200 mU/ml) were found in all patients with
rimary hepatic tumors and patients with primary
iliary cirrhosis. These 5 patients had a serum bili-
ubin above 8.0 mg/100 ml. The results suggest that
erum γ-glutamyl-transpeptidase is of diagnostic
alue in cirrhosis but is of limited use in monitor-
ng chronic hepatitis or in the follow-up of patients
fter biliary tract surgery.

052 PITFALLS IN THE ARTERIOGRAPHIC DIFFERENTIA-
TION OF INTRAHEPATIC AND EXTRAHEPATIC
ASSES. *(E.)* Shanser, J. D.; Glickman, M. G.;
Palubinskas, A. J. (Univ. California Sch. Med., San Francisco). *Am. J. Roentgenol. Radium. Ther. Nucl. Med.* 121(2):420-429, 1974.

Case reports are presented for 5 patients, all of whom had clinical evidence of an intrahepatic mass and 4 of whom had liver scans compatible with an intrahepatic mass. At surgery the diagnoses established were (1) carcinoma of the right adrenal gland with no gross or microscopic evidence of hepatic invasion; (2) a benign adrenal cyst which compressed the liver against the anterior abdominal wall; (3) a retroperitoneal metastasis from Wilm's tumor which did not involve the liver; (4) a cystic hypernephroma beneath a stretched and thinned right lobe of liver; and (5) a pancreatic pseudocyst situated behind the left lobe of the liver. Since these lesions were avascular or poorly vascularized and were directly superimposed upon the liver in the anteroposterior projection, arteriographic findings were inadequate to distinguish between intra- and extrahepatic masses. Despite the extrahepatic location of these lesions, intrahepatic arterial branches were stretched and attenuated. Identification of a "feeding" vessel was not possible because of the relatively avascular nature of these lesions. The extrahepatic location of 2 of these 5 masses was made by angiography by injecting the artery supplying the organ of origin of the mass. Abnormalities relating to the mass in arteries of the organ of origin indicated the correct diagnosis. It is suggested that a false-positive diagnosis of an intrahepatic mass can sometimes be avoided by careful analysis of intrahepatic arteries and by taking additional oblique or lateral projections, whichever is more tangential to the site of compression. Suspicion of the possible extrahepatic location of the mass should promote further investigation by intercostal, adrenal, pancreatic, or right renal arteriography.

7053 EFFECT OF ONE MEAL ON ENTEROHEPATIC CIRCULATION OF BILE SALTS. *(E.)* Low-Beer, T. S.; Wilkins, R. M.; Lack, L.; Tyor, M. P. (Duke Univ. Med. Ctr., Durham, N.C.). *Gastroenterology* 67(3):490-497, 1974.

The degree of interruption of the enterohepatic circulation of bile salts was studied in 7 patients (4 women and 3 men, aged 27-49 yr) with bile salt malabsorption after ileal resection with a double isotope method to circumvent the absence of steady-state conditions. All patients had undergone resections of the distal 1/3 to 1/2 of the ileum together with the ileocecal valve and, in most cases, the cecum and ascending colon. Measurements were made of the proportion of isotopically labeled pool of glycocholate and glycochenodeoxycholate present before a standard evening meal which was still present in fasting bile the following morning. In patients the proportion of glycocholate returned to the liver and biliary system *via* the enterohepatic circulation during this period averaged 5.8% of that returned by controls, while the equivalent value for glycochenodeoxycholate was 2.3%. The remaining small bowel of patients who had undergone ileal resection appeared unable to contribute significantly in maintaining enterohepatic circulation of conjugated bile salts. The bulk of such salts found in the gallbladder before breakfast had been synthesized overnight.

7054 THE LIVER IN AMYLOIDOSIS. *(E.)* Levy, M.; Polliack, A.; Lender, M.; Eliakim, M. (Hadassah Univ. Hosp., Jerusalem, Israel). *Digestion* 10(1):40-51, 1974.

A study was made of 21 patients with histological proof of hepatic amyloidosis (12 females and 9 males, aged 16-83 yr) in an effort to make diagnosis of this condition easier. In these 21 cases, diagnosis was established by autopsy in 17 cases and by liver biopsy in 4. The most consistent clinical finding was hepatomegaly and the most frequent laboratory feature was proteinuria due to associated renal amyloidosis. Electrocardiographic abnormalities and edema were found in more than 1/2 the cases, while clinical splenomegaly was encountered in 1/3. Ascites was rare and jaundice was unusual. Hypoalbuminuria, hyperglobulinemia, and high serum alkaline phosphatase were usually present. Clinical estimation of the size of the liver proved unreliable. Splenomegaly was detected clinically in 8 of the patients; however, at autopsy splenic amyloidosis was discovered in 82% and splenomegaly in 71% of the cases with an equal distribution among patients with primary and secondary amyloidosis. It is stressed that amyloidosis of the liver did not cause marked biochemical alterations in liver function. Serum vitamin B_{12} levels were measured in 3 patients and were elevated in all. It is concluded that the differentiation of 2 clinical syndromes of hepatic amyloidosis should be based on the histologic classification into intralobular and portal amyloidosis as opposed to the classification into primary and secondary forms. Intralobular and portal amyloidosis occurred equally among primary and secondary types. The former, less frequent, was associated with massive hepatosplenomegaly, cardiac involvement, ascites (all cases), and renal involvement (3 of 4 cases). The patients with highest serum alkaline phosphatase levels and the patient with severe jaundice were encountered in this group. The only death due to liver amyloidosis also had intralobular amyloidosis.

7055 GENETIC ASPECTS OF THE Pi SYSTEM. *(E.)* Cook, P. J. L. (Galton Lab., Univ. Coll. London, England). *Postgrad. Med. J.* 50(584):362-364, 1974.

Starch gel electrophoresis has shown that the plasma protein α_1-antitrypsin is polymorphic. At present 19 different alleles are known which are inherited in an autosomal pattern and constitute the Pi system. In the phenotype Pi ZZ, there is a virtual deficiency of plasma α_1-antitrypsin. About 1 baby in 3460 is born with α_1-antitrypsin deficiency, so about 230 such babies are expected in England and Wales each yr. Although an association between the deficiency and neonatal liver disease has been reported, not more than 10-15% of such babies should have liver disease. Of 26 Pi ZZ individuals who presented with out liver disease, none had a history of jaundice ar none had lost siblings in childhood due to liver disease.

7056 LECITHIN:CHOLESTEROL ACYLTRANSFERASE IN HUMAN LIVER DISEASE. *(E.)* Simon, J. B. (Dept. Med., Queen's Univ., Kingston, Canada). *Scand. J. Clin. Lab. Invest.* 33(Suppl 137):107-113, 1974.

Serum lecithin:cholesterol acyltransferase (LCAT) activity in 43 patients with parenchymal liver disease was assayed with autologous substrate. About 1/2 of the patients had active alcoholic disease, 1/3 viral hepatitis, and the rest various other parenchymal disorders. Esterifying activity ranged from undetectable to normal and averaged 10.4 μg/ml/ hr compared with 27.4 μg/ml/hr in 23 normal patients Of 15 patients with LCAT activity less than 5 μg/ml/ hr, 8 died within a week, while there were no deaths among those with higher activity. There was a negative correlation between LCAT and bilirubin, and in patients with hepatitis an inverse correlation between LCAT and SGOT. The data support the concept that low esterifying activity in liver disease reflects the overall severity of the hepatocellular dysfunction. In 23 patients simultaneous assays wit autologous substrate and with substrate prepared fr normal serum yielded identical LCAT values, indicating that abnormal substrate lipoproteins are not an important factor in decreased cholesterol esterification in hepatocellular disease. A comparison wa also made between LCAT activity in 12 patients with parenchymal liver disease and 6 patients with biliar obstruction. The results were in close agreement, whether measured by the method of Simon and Scheig or the method of Stokle and Norum. Although it has been claimed that combined determinations of LCAT and lipoprotein-X could differentiate between intrahepatic and extrahepatic cholestasis, recent data do not support this hypothesis.

7057 NEONATAL HEPATITIS SYNDROME AND ALPHA-1-ANTITRYPSIN DEFICIENCY: AN EPIDEMIOLOGIC STUDY IN SOUTH-EAST ENGLAND. *(E.)* Cottrall, K.; Cook, P. J. L.; Mowat, A. P. (King's Coll. Hosp. Med Sch., London, England). *Postgrad. Med. J.* 50(584): 376-380, 1974.

Of 100 cases of neonatal hepatitis syndrome observed over a period of 2 yr and 8 months, 21 patients had biliary atresia at laparotomy, 14 had hepatitis B antigen or antibody, and 13 had α_1-antitrypsin deficiency (Pi ZZ phenotype). In 49 cases no etiologi cal or associated factor was identified. All 13 patients (aged 7 months to 6 1/2 yr) with α_1-antitryps deficiency presented with jaundice, pale stools, and dark urine. Maximum recorded bilirubin ranged from 2-16 mg%. The jaundice persisted from 2 weeks to 6 months, and clearance was accompanied by raised seru aspartate transaminases and alkaline phosphatase.

4 of the 13 had hepatitis B antigen. Nine child-
re now clinically well, but 4 developed cirrho-
y age 1 yr and 2 of these have died. Maximal
malities of liver function tests were found in
patients with early onset of cirrhosis. Addi-
lly, age at onset of jaundice (2-10 days) and
uration (4-6 months) was longer in the 4 child-
eveloping cirrhosis by age 1 yr. In the 9 mild-
fected children, age at onset was 4-60 days, and
aundice persisted for 0.5-4 months. The patho-
al changes seen on liver biopsy in the first 6
s of life did not reflect the clinical course of
acute hepatitis in children with α_1-antitrypsin
iency. Four of the 9 mildly affected children
ave fibrosis on biopsy and a 5th has cirrhosis.
6 of the 48 patients with no identifiable etio-
al factor have evidence of fibrosis or cirrhosis
ver biopsy, as opposed to 8 of the 13 with α_1-
rypsin deficiency. The data indicate a poorer
osis for neonatal hepatitis patients with Pi ZZ
type than for patients with normal α_1-antitrypsin.

LIVER PHOSPHORYLASE DEFICIENCY IN GLYCOGENOSIS TYPE VI: DOCUMENTATION BY BIOCHEM-ANALYSIS OF HEPATIC BIOPSY SPECIMENS. *(E.)*

G.; Chuck, G.; Walling, L.; Schubert, W. K.
. Cincinnati Coll. Med., Ohio). *J. Lab. Clin.*
84(1):26-35, 1974.

and a girl (aged 4 and 7 1/2 yr, resp.) with
tomatic hepatomegaly demonstrated no hypergly-
response to epinephrine or glucagon, an ele-
n of SGOT and SGPT, and an increased concentra-
of hepatic glycogen, as well as a frayed appear-
of hepatic α-glycogen particles, and less than
f normal liver phosphorylase activity. In the
liver phosphorylase kinase activity was also
ed. Both children gave no evidence of a tumor
either had signs of hypoglycemia, acidosis,
ice, neurologic deficit, or muscle weakness.
of a diagrammatic scheme of the enzymatic cas-
in phosphorylase activation and deactivation
ciated with the interconversion of the active
nactive forms of this enzyme) indicated why low
ity of liver phosophorylase would be a nondiag-
c finding: defects in any of the enzymes in
ascade, as well as of phosphorylase itself,
result in low phosphorylase activity. Since
for phosphorylase activity on liver biopsy
mens involved active enzyme only, decreased lev-
f this form in the finding of low activity could
due to a deficiency of phosphorylase itself in
resence of a normal activating system, or to
ts in the activating system with the amount of
phosphorylase remaining normal. Thus, 2 sets
says are required. Results of such assays in
2 patients indicated low total phosphorylase
, liver phosphorylase deficiency), and not a
iency of the phosphorylase activating system of
iver. Attention is drawn to the fact that the
ng of low liver phosphorylase activity can
y be introduced as an artifact through examin-
of improperly prepared biopsy specimens or
psy tissue. It is suggested that the term gly-
osis Type VI be applied only to the condition
ose patients in whom the deficiency of liver
phosphorylase has been documented by low activity of both active and total liver phosphorylase.

7059 JAUNDICE ASSOCIATED WITH URINARY INFECTIONS IN PREGNANCY. *(Fr.)*

Monges, A.; Tronconi, J. C.; Legre, M.; Daoulas, H.; Serment, H.; Piana, L.; Ruf, H.; Blanc, R. (Hopital de la Conception, Marseille, France). *Med. Chir. Dig.* 2(6):345-350, 1973.

Of 15 pregnant women who developed jaundice in association with urinary infections, most were young and 7 were primigravidae. Symptoms developed during months 5 to 8 1/2 of pregnancy. Manifest symptoms of acute pyelitis were present in 12 cases. Blood bilirubin levels were about 50-60 mg/liter in most cases, and conjugated bilirubin predominated. Other symptoms included pruritis, anemia, asthenia, anorexia, weight loss, nausea, vomiting, abdominal distention, and chronic constipation. None of these patients developed toxemia of pregnancy, and all responded to treatment with antibiotics. Liver function tests were not very helpful in establishing the etiology of this jaundice: flocculation tests were negative in most cases, and while serum alkaline phosphatase, cholesterol, and lipid values were increased, the elevation was not significant. Although signs of hemolysis were found in some patients, the jaundice did not appear to be hemolytic in nature. Similar signs of hemolysis were also present in 6 of 9 pregnant women with urinary infections but no jaundice. A liver biopsy, obtained from 1 patient during cesarean section, revealed lesions similar to those described for bacterial jaundice: portal and periportal infiltrates, hepatocytic lesions, and signs of bile retention with intracanalicular thrombi. These findings and signs of cytolysis present in some patients suggest that the jaundice is due to bacterial hepatitis secondary to septicemia resulting from the urinary infection. Hormones secreted during pregnancy may aggravate cholestasis resulting from portal hepatitis and favor fixation of bacteria in the liver by slowing their hepatic transit. It is important to differentiate this form of jaundice from viral hepatitis, since prompt treatment helps reduce infant mortality. Of these 15 women, 9 had premature infants, 4 delivered at term, and 2 were lost to follow-up. Eleven infants were alive at birth and 2 were stillborn.

7060 HYPOPLASIA OF THE INTRAHEPATIC BILE DUCTS WITH A CLINICALLY BENIGN COURSE. *(Ger.)*

Luders, D. (Pediatr. Clin., Univ. Gottingen, Germany). *Monatsschr. Kinderheillkd.* 121(12):717-720, 1973.

Hypoplasia of the intrahepatic bile ducts was diagnosed in 6 boys who developed jaundice several days to 8 weeks after birth. One patient developed jaundice in the course of bronchitis and 3 others had urinary infections which responded to antibiotics.

Although intrahepatic cholestasis may favor the development of pyelonephritis, it is more likely that the association of these 2 diseases is fortuitous. One infant had Down's syndrome and another was born prematurely. Liver biopsies, taken during the first few months of life, demonstrated the absence of bile ducts, at least in some of the portal fields examined. Isolated giant cells and round cell infiltrates were detected in the portal fields in 2 of these 6 infants. The ^{125}I-bengal rose test confirmed that the bile ducts were not completely blocked: from 7.1 to 82.0% of the dye was excreted in the stool in 5 days. Bilirubin levels normalized 3-4 months after birth in 5 patients, but the remaining child still has a slightly elevated value at age 2.5 yr. These findings suggest that hypoplasia of the intrahepatic bile ducts is due to retarded development of the bile ducts, rather than to neonatal hepatitis with intrahepatic cholestasis or to malformations associated with atresia of the extrahepatic bile ducts (MacMahon-Thannhauser syndrome).

7061 INTRAHEPATIC BILIARY FIBROADENOMATOSIS.

(Fr.) Auvert, J.; Weisgerber, G. (H. Mandor Hosp., Paris, France). *Med. Chir. Dig.* 2(6):363-373, 1973.

To gain more information on the pathology and clinical course of intrahepatic biliary fibroadenomatosis, 22 patients (12 females and 10 males) were followed for 1-28 yr. All 22 children had splenomegaly and portal hypertension, and 20 presented at age 1-14 yr (mean 7 yr) with hematemesis. After shunt surgery, performed 19 times on 18 children, esophageal varices disappeared and there was no recurrence of bleeding in 15 cases. Splenorenal shunts became obstructed in 2 cases: 1 patient died of recurrent bleeding and the other recovered after a portacaval shunt was performed 6 months later. Of the 4 unoperated patients, 2 had no signs of bleeding, 1 developed hepatic coma after a severe hemorrhage and died, and 1 had severe kidney failure due to polycystic kidneys. Portal hypertension was responsible for 3 deaths. When they were first examined, 21 patients had hepatomegaly, but liver function tests were normal or almost normal. Collagenous fibrosis of the portal spaces was found in 20 surgical liver biopsies. This fibrosis extended perilobularly, joining Kiernan's spaces, but never reached inside the liver lobules which were normal in structure. Both small and ectatic bile ducts were involved. Autopsies performed on 5 children who died revealed that the extrahepatic biliary tract was hypertrophied, possibly as an adaptation to proliferation of intrahepatic bile ducts and increased bile flow. Severe cholangitis developed in 3 patients, and 2 of them died. Gross examination showed dilatation of the superinfected intrahepatic biliary tract: large cavities limited to the left lobe in one case and diffuse ectasias, and about 1 cm in diameter, in the other. Although both patients had undergone shunt surgery, 4 months and 9 yr before, resp., neither gross examination of the liver nor microscopic examination of liver biopsies showed a
evidence of this. None of these 22 patients died
hepatocellular failure; a 13-yr-old girl who died
with severe jaundice had intercurrent viral hepatit
Morphological kidney anomalies were found in 19 of
22 children although kidney function remained unch

7062 INTRAHEPATIC CHOLESTASIS IN CHRONIC VENO CONGESTION.

(Cz.) Chlumska, A. (Med.
Charles Univ., Prague, Czechoslovakia). *Cesk. Gast
enterol. Vyz.* 27(8):532-534, 1973.

Autopsies performed on 70 patients (36 men and 34
en, aged 46-87 yr) with histories of chronic cardi
insufficiency revealed that 17 (24%) had intrahepat
cholestasis. These included 11 of the 51 with coro
nary atherosclerosis, 4 of the 11 with rheumatic h
disease, and 2 of the 8 with chronic cor pulmonale.
Histological examination of the liver showed that
pigment was present in the form of thrombi in bile
capillaries near the central veins or, in a few ca
as intracytoplasmic granules in liver cells adjace
to the central veins. All of those examined had m
derately severe steatosis, but the extrahepatic bil
ary tract was intact in all subjects with cholestasis. Intrahepatic cholestasis was diagnosed in 7
53 patients with moderate hepatic venostasis, in 8
the 13 with congestion, and in 2 of the 4 with hep
tic fibrosis. Hemorrhagic infarcts were present i
the lungs of 8 of the 70 autopsied patients, and 6
these 8 patients had intrahepatic cholestasis. It
concluded that intrahepatic cholestasis in patient
with chronic cardiac insufficiency results from hy
oxic damage to the liver cells.

7063 SYNTHESIS AND EXCRETION OF BILE ACID SUL FATES: AN IMPORTANT PROTECTIVE MECHANIS IN CHOLESTASIS.

(Ger.) Stiehl, A. (Med. Clin.,
Univ. Heidelberg, Germany). *Verh. Dtsch. Ges. Inn
Med.* 79:948-950, 1973.

Sulfated and nonsulfated bile acids were determine
in urine and serum from 10 patients with extrahepa
tic biliary obstructions, 10 with hepatitis, 10
with cirrhosis, and 4 with cirrhosis and kidney
failure. No significant differences were found be
tween the mean urinary excretion of nonsulfated
bile acids in patients with extrahepatic biliary
obstructions (19.2 ± 18.9 mg/day), hepatitis (9.28
± 6.01 mg/day), and cirrhosis (12.29 ± 9.58 mg/day
but patients with cirrhosis and kidney failure excreted significantly more (75.01 ± 25.00 mg/day)
these bile acids than did the other 3 groups. Uri
nary excretion of sulfated bile acids averaged 25.
± 24.94 mg/day in extrahepatic biliary obstruction
12.70 ± 7.0 mg/day in hepatitis, 20.56 ± 26.74 mg/
day in cirrhosis, and 15.87 ± 16.75 mg/day in cirrhosis and kidney failure. Thus, in all patients
except those with cirrhosis and kidney failure, mo
than 50% of bile acids were excreted in the urine
their sulfate esters. The concentration of nonsul

ed bile acids in serum was about 10 times higher
that of sulfated bile acids in all 4 groups.
significant differences were found between the 4
ps of patients studied. In a patient with neo-
stic biliary obstruction and progressive chole-
sis, measurements made on 5 successive days
ed an increase in the relative percentage of
fated bile acids from 23.4% to 64.5%. On the
er hand, the relative percentage of sulfated bile
ds decreased from 46.2% to 14.3% over a 5-day
iod in a patient with regressing cholestasis which
been caused by cholangitis.

4 BENIGN VASCULAR TUMORS OF THE LIVER IN CHILDREN. *(Dut.)* Gerards, L. J.; van
rom, C. G.; Voute, P. A. (Wilhelmina Children's
., Utrecht, Netherlands). *Ned. Tijdschr. Gen-
d.* 117(44):1633-1637, 1973.

e reports are presented for 4 infants (3 girls
1 boy, aged 2-9.5 months) with vascular tumors
the liver. The first clinical symptom was ab-
inal swelling in all 4 cases. Hepatomegaly was
d in 3 patients and 1 had a tumor in the upper
omen, the origin of which could not be esta-
shed. Two patients had gastrointestinal symptoms,
d cardiac decompensation, and 3 had decreased
oglobin values; but only 1 had jaundice. This
ient, who did not have cardiac decompensation,
severe disturbances in liver function as a re-
of extrahepatic biliary obstruction and liver
damage. On auscultation of the abdomen above
liver, a murmur was detected in 2 cases. At
rotomy 2 of the patients had hemangioendotheli-
s and 2 had hemangiomas of the liver; in addition,
tient had an hemangioma of the skin. The diag-
is was confirmed by histological examination of
sies in 3 cases. Telecobalt therapy (500 rads
n in 10 sessions over a 14-day period) was used
essfully on 2 patients who are alive and well
yr and 10 months after treatment, resp. A large
e of radiation (1830 rad on the right and 1820 on
left in 36 sessions over 6 weeks) was adminis-
ed to another patient who received additional
iation for an hemangioma of the skin; this pa-
nt is alive and well 2 yr after treatment. The
aining patient, who had extrahepatic biliary ob-
uction, is alive and well at age 3 yr after ad-
istration of megavolt therapy (600 rad over the
er and 3100 rad over the probable tumor region in
-week period).

5 CURRENT APPROACH TO THE TREATMENT OF HEPATIC METASTASES OF CANCER. *(Fr.)* Gautier-
oit, C.; Luez, J.; Vermesse, G.; Duwat, G. (Munic. Hosp., Lens, France). *Lille Med.* 18(10):1271-1275, 1973.

Of 4 patients who underwent surgery for hepatic metastases, 2 died postoperatively of acute liver failure and after 2 operations necessitated by an acute duodenal ulcer and evisceration, resp. The 2 remaining patients survived for 98 days and 2 yr; in the latter case, surgery was supplemented by intra-arterial chemotherapy for a recurrence which developed 16 months after surgery. It is concluded that surgery should be reserved for solitary hepatic metastases located in the left lobe. One patient who underwent complete dearterialization of the liver died 36 hr after surgery in a coma and with diffuse bleeding consistent with acute liver failure. Of 6 patients who underwent truncal ligation of the hepatic artery, 2 died postoperatively of acute respiratory failure and cardiovascular complications, resp. Liver function returned to normal and hypochondrial pain disappeared, but hepatic scintigraphy showed no regression of the metastases in the remaining 4 patients. Two of these patients died after 7 and 8 months, resp., and 2 are still alive 9 and 10 months, resp., after surgery. Continuous perfusion of the hepatic artery for 3-6 weeks with a complex sequence of 5-fluorouracil, thio-TEPA, vinblastine, methotrexate, actinomycin or mitomycin, and ametycin was performed on 3 patients who died after 15-20 days of myocardial infarction (2 cases) and pulmonary embolism (1 patient), possibly due to use of mitomycin. Before they died, marked subjective improvement was noted in 2 cases and regression of hepatomegaly in 1. Combined intra-arterial chemotherapy and truncal ligation of the hepatic artery in 2 cases induced subjective improvement in both patients and produced regression of the lesions in 1. One patient died after 6 months and the second is alive 4 months after completion of treatment.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

JAUNDICE, HYPERTROPHIC PYLORIC STENOSIS,
AND HEPATIC GLUCURONYL TRANSFERASE. *(E.)*
ley, M. M.; Felsher, B. F.; Asch, M. J.; Carpio,
Isaacs, H. (Childrens Hosp. Los Angeles, Calif.).
ediatr. Surg. 9(3):359-364, 1974.

s of hypertrophic pyloric stenosis and concomitant
dice are reviewed. Two causes of jaundice are
idered possible in these cases: first, the
ssive production of bilirubin, and secondly, de-
ive transport and conjugation of free bilirubin.
ach of 12 infants with hypertrophic pyloric sten-
, a serum bilirubin determination was performed
re pyloromyotomy. Of the 12 patients, 5 were
rly jaundiced and 7 were not. The jaundiced
ents had hepatic glucuronyl transferase activity
een 60-180 μg/conjugated/bilirubin/g of liver/hr,
ompared with 520-800 μg in patients without jaun-
. In both groups of patients, microscopic findings
ed increased hepatic glycogen content, hemato-
sis, and hemosiderosis. The only recognized
cidental clinical diseases were phenylketonuria
patient and microcephaly in another. It is
ent that the jaundiced infant with hypertrophic
ric stenosis and jaundice has less hepatic glucur-
transferase activity than the nonjaundiced pa-
t with hypertrophic pyloric stenosis. The reason
this decrease is not known although decreased ca-
c intake could be a factor.

NAVAJO JAUNDICE: A VARIANT OF NEONATAL
HYPERBILIRUBINEMIA ASSOCIATED WITH BREAST
ING. *(E.)* Saland, J.; McNamara, H.; Cohen, M.
Montefiore Hosp. Med. Ctr., Bronx, N.Y.). *J.*
atr. 85(2):271-275, 1974.

inical and chemical analysis of 47 Navajo neo-
s demonstrated a high incidence of unconjugated
rbilirubinemia during days 1-4 compared with
lack, Puerto Rican, and white control neonates.
vidence of isoimmunization was found in 40 of
Navajo infants, and the controls were also free
soimmunization problems. The mean daily serum
rubin concentration in the control group in-
sed from just above 3 mg/100 ml on day 1 to a
imum of 5.5 mg/100 ml on day 2. Within the
jo group, the 8 bottle-fed infants had an ini-
serum bilirubin concentration of 8.4 mg/100 ml
concentrations appeared to plateau at 9.4 mg/100
on day 2. In the 39 breast-fed infants, concentrations rose continuously from 7.5 mg/100 ml on day 1 to reach 14.5 mg/100 ml on day 4. No data were available after day 4 for the majority of babies. The mean breast-milk inhibition of bilirubin glucuronyl transferase activity in rat liver homogenates was 29.9% for Navajo breast milk *versus* 3.8% for control milk. The higher the bilirubin concentration in any individual baby, the greater the inhibitory activity of its mother's milk. Assays to determine the cause of neonatal jaundice in nonbreast-fed infants showed no inhibitor of bilirubin glucuronyl transferase in maternal, cord, or newborn infant sera. It is suggested that genetic and/or environmental factors are significant in the etiology of jaundice in Navajo neonates.

7096 EFFECT OF PHENOBARBITAL ON LIVER FUNCTIONS IN PATIENTS WITH DUBIN-JOHNSON SYNDROME. *(E.)* Shani, M.; Seligsohn, U.; Ben-Ezzer, J. (Chaim Sheba Med. Ctr., Tel Hashomer, Israel). *Gastroenterology* 67(2):303-308, 1974.

In 13 patients (10 men and 3 women, aged 20-62 yr) with Dubin-Johnson syndrome, treatment with phenobarbital (100 mg 3 times/day) for 2 weeks significantly decreased plasma levels of total and direct bilirubin. Values decreased from pretreatment means of 3.28 to 2.41 mg/100 ml and from 2.06 to 1.44 mg/100 ml, resp. The transport maximum of BSP increased significantly from a mean of 0.35 before treatment to 0.67 mg/min. However, these effects were variable, and some patients did not respond to phenobarbital. The usual Dubin-Johnson pattern of corpropor-phyrin excretion in the urine as well as the plasma levels of factor VII were virtually unaffected by this drug. The findings support the theory that phenobarbital not only induces enzymes involved in hepatic drug metabolism, but also enhances biliary excretion of various compounds.

7097 BETA-GLUCURONIDASE IN DUODENAL BILE OF JAUNDICED NEWBORN INFANTS TREATED WITH PHOTOTHERAPY. *(E.)* Lund, H. T.; Petersen, I. (Glostrup Hosp., Denmark). *J. Pediatr.* 85(2):268-270, 1974.

Duodenal bile was analyzed for β-glucuronidase concentration in 10 newborn infants (5 male and 5 female, aged 3-7 days) with hyperbilirubinemia (≥ 100 mg/liter) but without signs of isoimmunization. Five infants received phototherapy for 24 hr after the 1st bile sampling while 5 served as controls. The light unit was equipped with 8 blue 20 watt fluorescent bulbs, with irradiating energy at the infant level of 9 watt/m^2 (B)^5. Four additional 24-hr bile samples were analyzed after the experimental period. A significant decrease in mean β-glucuronidase activity was observed in the 2nd bile sample of both groups, but no significant difference was evident between treated (7.0 initially to 3.7 μmol/hr/liter) and untreated (7.8 to 4.7) infants. The bilirubin values increased at the 2nd reading in treated infants (from 109 to 120 mg/liter) and in controls (from 130 to 137), but in the next two 24-hr samples, decreased to final levels of 87 and 109, resp. This study demonstrated that phototherapy has no influence on the activity of β-glucuronidase in duodenal bile.

7098 PHOTOTHERAPY AND BARBITURATE TREATMENT FOR NEONATAL JAUNDICE. *(Ger.)* Obal-Nagy, M.; Thurzo, L.; Meszaros, J. (Med. Univ., Szeged, Hungary). *Acta Paediatr. Acad. Sci. Hung.* 14(3/4):201-207, 1973.

Serum bilirubin levels were determined daily on days 1-8 in 134 mature neonates whose bilirubin levels lay within the physiologically normal range. These newborns were divided into 5 groups: (1) 36 untreated controls, (2) 23 treated by whole-body irradiation with light (420-450 nm, intensity of 300 lux) alone for 8 days, (3) 25 treated with phenobarbital (5 mg/kg/day i.m. divided into 2 doses) alone for 8 days, (4) 30 given phototherapy on days 1-8 and phenobarbital on days 3-8, and (5) 20 given both phototherapy and phenobarbital on days 1-8. Serum bilirubin levels were decreased by both phototherapy and phenobarbital. While the effect of low-intensity illumination was not significant, administration of phenobarbital alone had a significant effect on bilirubin levels from day 5 on. In group (4) bilirubin levels were significantly decreased on day 8 and in group (5), on day 3. No side effects were observed with phototherapy or with the dose of phenobarbital employed. Treatment reduced the necessity for exchange transfusions by almost 80%.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

7099 SEVERE INTRAHEPATIC CHOLESTASIS DUE TO THIABENDAZOLE. *(E.)* Jalota, R.; Freston, J. W. (Univ. Utah Coll. Med., Salt Lake City). *Am. J. Trop. Med. Hyg.* 23(4):676-678, 1974.

A 32-yr-old woman developed severe and protracted intrahepatic cholestasis following a 4th dose of thiabendazole (25 mg/kg/day p.o.), given for prophylaxis against pinworm infestation. The cholestatic reaction was associated with nausea, intense pruritus, and a generalized rash. Despite prednisone treatment (4 mg/day), the jaundice persisted for more than 1 month without signs of remission. Laboratory findings indicative of cholestasis included alcoholic stools, urine bilirubin, and elevated serum conjugated bilirubin, alkaline phosphatase, cholesterol, and β-globulin fraction. A percutaneous transhepatic cholangiogram was followed by a massive intra-abdominal hemorrhage which led to death before the abdomen could be opened. Autopsy showed 2 needle puncture sites on the anterior-superior surface of the liver, 1 communicating with a hepatic vein. Liver photomicrographs revealed severe central cholestasis with bile pigment in hepatocytes, and numerous Kupffer cells and bile plugs. Portal areas showed increased numbers of mononuclear cells and eosinophils. The appearance was compatible with a drug-induced hypersensitivity type of cholestatis.

7100 HEPATOCELLULAR DYSFUNCTION WITHOUT JAUNDIC AFTER ENFLURANE ANESTHESIA. *(E.)* Denlinger, J. K.; Lecky, J. H.; Nahrwold, M. L. (Natl. Inst. Health, Bethseda, Md.). *Anesthesiology* 41(1): 86-87, 1974.

A 40-yr-old man with multiple endocrine adenomatosis (Sipple's syndrome) underwent 5-hr surgery for excision of a mass in the neck and radical neck dissection. Initial thiopental anesthesia (500 mg) was followed by enflurane maintenance (1.5-2.5% in nitrous oxide with 50% oxygen). Four hr postoperatively, body temperature increased, with spikes as high as 39 C (oral) over the next 10 days; this was accompanied by anorexia and general malaise. Liver function tests SGPT and SGOT rose to markedly abnormal levels while total bilirubin increased slowly to the upper limit of normal. The eosinophil count increased from 1% to 6% on the 3rd day and remained above normal for 2 weeks. Hepatitis B antigen was negative by radioimmunoassay, and hepatitis B antibody was not detected by passive hemagglutination. Fifteen days after surgery, antimitochondrial antibodies were not present; studies of lymphocyte transformation done at this time were negative. Liver biopsy was not performed. Upon discharge on the 21s day, the patient had recovered fully except for mild malaise and minimal elevation of SGOT and SGPT.

ght yr before this admission, the patient had bi-
teral adrenalectomy and total thyroidectomy with
lothane anesthesia for both. At that time, no cli-
cal evidence of hepatic injury was observed; both
OT and bilirubin levels were normal. Although
sidual halothane in the anesthetic apparatus may
ve precipitated the hepatic abnormalities in this
tient, the results suggest an allergic response to
flurane.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

115 HEPATITIS B ANTIGEN IN VIRAL HEPATITIS IN WEST LONDON. *(E.)* Farrow, L. J.; Lamb,
. G.; Coghill, N. F.; Lindon, R. L.; Preece, J.;
uckerman, A. J.; Stewart, J. S. (Watford Gen. Hosp.,
ngland). *Br. Med. J.* 3(5923):83-86, 1974.

n a 12-month study, 215 patients (129 men and 86
omen) with viral hepatitis were followed until clin-
cal and biochemical recovery and clearance of antigenemia. The median period of antigenemia was 7 weeks (mean 8.5 weeks). Parameters examined were serum bilirubin, alkaline phosphatase, and alanine amino transferase, as well as hepatitis B antigen (HBAg). The vast majority of patients exhibited febrile or gastrointestinal illness and dark urine followed by jaundice. Of the 215 patients, 32 (15%) were positive for HBAg. Since all 60 patients below 15 yr were negative, 21% of the subjects aged 15-

69 yr were antigen positive. Of 81 patients thought to have acquired their infection parenterally, 18 (22%) were HBAg positive. Four (17%) of 23 with a history of exposure to both ingestion and parenteral infection were positive, while only 10 (14%) of 70 with no known history of exposure to either mode of infection were positive. None of 41 patients with a definite exposure by ingestion was positive. In the parenteral group, the incidence of HBAg positive was greater in those with nontherapeutic than with therapeutic skin punctures, and 2 of 4 drug addicts as well as 2 of 4 tattooed patients were HBAg positive. The overall ratio of male (129) to female (86) patients was 1.5/1, but more than 5 times as many men (27) as women (5) were HBAg positive. Nearly half of these positive males were in the parenteral group though most of these exposures involved the use of disposable equipment during vaccinations, inoculations, and dental anesthetic. In the group without a known history of exposure, only males were positive. Male preponderance may be due to sex differences in susceptibility to infection. The 20-39 yr age groups accounted for 19 of the 27 positive men and all but 1 of the 5 positive women, demonstrating predominance in young adults. Sixty of 85 children (70%) were tested for HBAg as compared with 95% of adults (155 of 163), which could lead to underestimation of the proportion of children in this survey. Of the total patients with hepatitis, 35% were under 15 yr (86 patients), but only 28% of those tested for HBAg were children. Therefore the possibility cannot be excluded that HBAg might have been present in some of the children not tested.

7116 PLATELET AGGREGATION AND CRYO-IgM IN THE STUDY OF HEPATITIS AND IMMUNE COMPLEX STATES.

(E.) Penttinen, K.; Wager, O.; Rasanen, J. A.; Myllyla, G.; Haapenen, E. (Dept. Virol., Univ. Helsinki, Finland). *Clin. Exp. Immunol.* 15(3):409-416, 1973.

Hepatitis and other sera were studied for direct platelet aggregating activity in non-heated and heat-treated state, for inhibition of platelet aggregation by antiglobulin active cryoglobulin IgM components, and for sedimentation velocity of platelet aggregation activity by sucrose gradient centrifugation. Three distinct patterns of direct platelet aggregating activity were established: 1) 'aggregated IgG type': heating-dependent, greater than or equal to 19S, inhibitable by cryoglobulin IgM, serum anticomplementary; 2) 'antibody type': heating-dependent, 7S and/or 19S, non-inhibitable by cryoglobulin IgM, serum not anticomplementary; and 3) 'immunecomplex type': heating-independent, greater than or equal to 19S, inhibitable by cryoglobulin IgM, anticomplementary activity present or absent. In the heavy platelet aggregating-active sucrose gradient serum fractions of one patient with persistent cholangiolitic hepatitis, only IgG4 GM markers were detected.

7117 THE SYNDROME OF HEPATITIS AND APLASTIC ANAEMIA.

(E.) Ajlouni, K.; Doeblin, T. D. (Dept. Med., State Univ. N.Y., Buffalo). *Br. J. Haematol.* 27(2):345-355, 1974.

In the literature, 88 cases have been described of severe pancytopenia closely following the onset of apparently typical viral hepatitis. Two additional cases are reported. A 19-yr-old girl was hospitalized with jaundice and elevated serum bilirubin, SGOT, and SGPT. The serum was negative for hepatitis-associated antigen. After 15 days of treatment the patient was discharged but was readmitted 11 weeks later with recurrent jaundice and elevated bilirubin and SGOT values. Petechiae were observed 3 days later and the platelet count was 40,000/ml. Prednisone (30 mg/day) was prescribed but the patie had to be hospitalized a 3d time for hemorrhagic phenomena. The hemoglobin was 9.4g/dl, the packed cell volume 27%, WBC 1,000/ml, and no platelets were found. Bone marrow aspiration gave a hypocellular specimen with 90% lymphocytes. Treatment consisted of 100 mg of oxymetholone and 120 mg/day prednisone. Despite multiple blood and platelet transfusions the patient's condition deteriorated; she developed staphylococcal sepsis and died 3 week after admission. At autopsy, the liver showed early posthepatic fibrosis around the centrilobular veins and the periphery of the lobules; no evidence of active hepatitis was present. Similar findings are reported for a 15-yr-old boy who died of subarachnoid hemorrhage despite blood transfusions, prednisone, and oxymetholone; no autopsy was performed. The general features of this syndrome are the rapid and high mortality (88%) and an age and sex distribution parallel to that of hepatitis, unlike other series of aplastic anemia. Although viral damage to hematopoietic cells can be demonstrat *in vitro*, chromosomes in these patients were normal after short-term culture of peripheral lymphocytes. Therapeutically, androgens may be of some benefit despite the high mortality. No adequate explanatio for the association is available, but infectious hepatitis should be accepted as a potential cause of aplastic anemia.

7118 RESULTS FROM A STUDY OF CORTICOSTEROID EXCRETION IN INFECTIOUS HEPATITIS BY INTR VENOUS INJECTION OF 4-^{14}C HYDROCORTISONE.

(Rus.) Matveyev, A. (Vitebsk Med. Inst., USSR). *Ter. Arkh* 46(3):103-107, 1974.

4-^{14}C Hydrocortisone was infused i.v. for 30 min (1 μC, about 7 μg/100 ml of 5% glucose solution) in 9 patients with infectious and serum hepatitis and in 3 controls. The urine was collected for 2 days after infusion. One patient was given radioactive isotope twice: at the peak of the disease and before discharge from the hospital. After the first infusion 920,000 pulses/min were excreted during th first 24 hr; 91,000 pulses/min were excreted on the 2nd day and 124,000 pulses/min on the 3rd. After t 2nd infusion performed during convalescence, 1,546, pulses/min were excreted during the first 24 hr and 84,000 pulses/min on the 2nd day. To test the effe of prednisolone treatment, 3 patients received 2 in

ions of ^{14}C hydrocortisone each — before predniso-
e treatment and on the 2nd-4th day after treat-
t. The patient with the highest (82%) retention
the isotope showed a 4-fold increase of excretion
er treatment while excretion remained unchanged
the other 2 patients with pre-prednisolone retention
15% and 25% resp. Retention was highest during
first 24 hr after infusion. The low level of
ticosteroid excretion with urine can be explained
retention of some corticosteroids in the body and
the depression of the glucocorticoid function of
adrenal glands.

9 TRANSMISSION OF AUSTRALIA ANTIGEN BY INSECTS
[Periplaneta (Blatta) americana]: A POSSI-
ROUTE OF INFECTION FOR SERUM HEPATITIS. *(Ger.)*
e, H.; Sanwald, R.; Ritz, E. (Med. Clin., Univ.
delberg, Germany). *Verh. Dtsch. Ges. Inn. Med.*
1633-1635, 1972.

group of American cockroaches *(Periplaneta ameri-*
a) received injections of Australia antigen (AuAg)-
itive serum in the coelomic cavity while others
e infected p.o. by injection of AuAg-positive serum
o the gastrointestinal tract through a microtube.
trols were given injections of physiological saline
the coelomic cavity. The secretion ("vomitus")
ch cockroaches produce as a defensive reaction when
y are handled was collected on filter paper, as
aspirated hemolymph and saline from the controls.
filter paper was rinsed with physiological saline
ch was then concentrated and passed through a col-
charged with antibodies to AuAg. AuAg was studied
the hemolymph by electrophoresis and the complement-
ation test. High titers of AuAg were detected in
hemolymph and vomitus of cockroaches given injec-
ns of AuAg-positive serum in the coelomic cavity
the gastrointestinal tract. Since *P. americana*
taminates kitchen equipment and foods with its
retion, it may act as a vector in transmitting
rum hepatitis.

Chronic Hepatitis

7132 PSEUDO-TUMOR OF THE LIVER IN HEPATITIS.

(E.) Raouf, R.; Stebner, F. C. (Dept. Radiol., Wayne State Univ., Detroit, Mich.). *J. Am. Med. Wom. Assn.* 29(6):262-264, 1974.

A 68-yr-old woman with a 1-week history of fever, chills, and nausea was hospitalized. Chest x-ray findings were compatible with left lower lobe pneumonia and mild cardiac failure, and abdominal examination revealed moderate hepatomegaly; SGPT and alkaline phopshatase values were elevated. Although the patient responded to treatment with digitalis, diuretics, and penicillin, no change occurred in the size of the liver, and hepatomegaly appeared to be out of proportion to the degree of cardiac failure. A liver scan revealed moderate hepatomegaly with 2 discrete areas of decreased radioactivity, posteriorly in the right lobe and around the hepatic portal, which were thought to be neoplastic. However, upper gastrointestinal and barium enema examinations, cholecystogram, i.v. pyelogram, sigmoidoscopy, and a bone survey were all negative. A liver biopsy showed changes compatible with chronic hepatitis. Fibrosis and inflammatory cell infiltration were found, but no fatty infiltration was present, A 2nd liver scan, obtained 3 1/2 months after the first, revealed that the liver was much smaller and showed no filling defects. Instead, the area in the right lobe appeared to have increased activity, suggesting more severe cellular damage in the remainder of the liver. A 3rd scan, obtained 7 months after the first, showed that the liver was normal in size. Isotope activity was evenly distributed in the anteroposterior view, while mild patchy distribution was present in the bottom of the right lobe in the lateral view. This case demonstrates the value of serial scanning in differentiating between the pseudotumors of cirrhosis and chronic hepatitis and true space-occupying lesions of the liver, such as hepatoma, metastases, or cysts.

7133 DETECTION OF LYMPHOCYTES WITH INCREASED DNA-SYNTHESIS IN THE PERIPHERAL BLOOD OF PATIENTS WITH ACTIVE CHRONIC HEPATITIS. *(E.)*

Maerker-Alzer, G.; Schumacher, K.; Gross, R. (Med. Clin., Univ. Cologne, Germany). *Klin. Wochenschr.* 52(4):190-193, 1974.

Peripheral blood lymphocytes from 76 patients with active chronic hepatitis and 48 healthy donors were exposed to ^{14}C-thymidine (2 μC) for 2 hr. The basic metabolic rate of control lymphocytes corresponded to a ^{14}C-thymidine uptake which averaged 46 cpm. A similar uptake was observed in 52 patients, but in 24 cases the uptake of label averaged 290 cpm. Compared with patients with a normal basic metabolism of lymphocytes, the patients with elevated metabolism had significant increases in immunoglobulins G, A, and M, and a greater frequency of antibodies against nuclei, glomeruli, and small arteries of the kidney. The 2 groups of patients did not differ in occurrence of hepatitis associated antigen (HAA) or anti-HAA. Fourteen patients with elevated lymphocyte metabolism were available for follow-up. In 10 the elevation persisted and all died within 15 weeks due to the rapid progress of hepatitis. In the 4 survivors, there was a gradual return of lymphocyte metabolism rate to normal. It is suggested that *in vivo* activated lymphocytes are mediators of specific immunity, analogous to the graft rejection reaction. The rapid progress of disease in the patients with persistent elevated lymphocyte metabolism supports this hypothesis.

7134 ANTI-GLOMERULAR ANTIBODY IN CHRONIC ACTIVE AND CHRONIC PERSISTENT HEPATITIS. *(E.)*

Levy, R. L.; Hong, R. (Ctr. Hlth. Sci., Univ. Wisconsin, Madison). *J. Pediatr.* 85(2):155-158, 1974.

Indirect immunofluorescent techniques were used to test for smooth-muscle antibodies, anti-glomerular a tibodies, and compliment fixation on sera from 12 patients with chronic active hepatitis (8 females and males) and 7 with chronic persistent hepatitis (5 females and 2 males). The diagnosis was established b examination of percutaneous liver biopsies in all but 4 patients with chronic active hepatitis and severe clotting disorders, but all 4 had typical clinical and laboratory evidence of the disease with histories dating back longer than 2 yr. Ages at the time of diagnosis ranged from 5 to 15 yr. In all but 2 cases serum samples were obtained within 3 months of the onset of symptoms and after the diseas had persisted for an average of 25 months. Sera fro all 12 patients with chronic active hepatitis contained both anti-glomerular and smooth-muscle antibodies, while 5 of the 7 patients with chronic persistent hepatitis had smooth-muscle antibodies but none had anti-glomerular antibodies. In all patient both types of antibodies were of the IgG class. Non of the antibodies was complement fixing. There was no difference in results obtained from early samples and those obtained later. Only 1 patient had evidence of renal disease; he had interstitial nephriti which began at about the same time as the chronic active hepatitis. Anti-glomerular antibody in sera from patients with chronic active hepatitis was completely absorbed on a suspension of renal glomeruli, while smooth-muscle antibodies were not, suggesting that 2 separate antibodies are present. Thus, there appears to be an additional antibody response in patients with chronic active hepatitis. It is suggest that the test for anti-glomerular antibody may be a useful serological method to differentiate between these 2 forms of chronic hepatitis.

135 CELLULAR IMMUNE REACTIONS TOWARD HOMOLOGOUS
LIVER-SPECIFIC ANTIGENS (HLP) IN CHRONIC
EPATITIS. *(Ger.)* von Meyer zum Buschenfelde, K. H.;
nolle, J.; Berger, J. (Med. Clin., Univ. Mainz, Ger-
any). *Klin. Wochenschr.* 52(5):246-248, 1974.

ellular immunity to homologous, liver-specific pro-
eins was assayed in 100 patients with chronic in-
lammatory liver disease by using a two-phase leuko-
yte migration test. This technique employs a mix-
ure of liver-specific antigens consisting of a hepa-
ocellular membrane antigen (30-40%), a soluble cyto-
lasmic liver antigen (about 30%), and 3-4 plasma pro-
eins synthesized in the liver (<1-8% each). Patients
onsisted of 15 who had viral hepatitis more than 6
onths previously; 9 with chronic persistent hepati-
is; 34 with chronic active hepatitis (untreated); 23
ith histories of chronic active hepatitis dating back
ore than 1 yr who were receiving azathioprin (1.5 mg/
g/day) and prednisone (5-10 mg/day); and 19 with ac-
ive, progressive cryptogenic cirrhosis. Leukocyte
igration was significantly inhibited in 29 of the 34
atients with untreated chronic active hepatitis and
n 8 of 19 patients with cirrhosis, but in only 4 of
3 patients receiving immunosuppressives for chronic
ctive hepatitis, 2 of 15 posthepatitic patients, and
of 9 with chronic persistent hepatitis. Since leu-
ocyte migration was inhibited primarily in patients
ith hypergammaglobulinemia, cell-mediated immune re-
ctions toward liver-specific antigens would appear to
lay an important role in the pathogenesis of chronic
ctive hepatitis. Further research is necessary to
stablish whether this technique is suitable for dis-
inguishing between early stages of chronic progres-
ive liver inflammation and acute hepatitis.

136 THE THERAPEUTIC EFFECTIVENESS OF VITAMIN
A IN LIGHT-DARK ADAPTATION AND DISORDERS
N COLOR VISION IN CHRONIC LIVER DISEASE. *(Ger.)*
lein, S.; Dokert, B.; Marre, E.; Renger, F.; West-
rmann, K. (Carl Gustav Carus Med. Acad., Dresden,
ermany). *Z. Gesamte Inn. Med.* 29(12):484-487, 1974.

phthalmologic tests were performed on 25 patients
ith chronic persistent hepatitis, 25 with chronic
ggressive hepatitis, and 25 with cirrhosis to deter-
ine whether there was any correlation between the
everity of the liver disease, on one hand, and vita-
in A levels, the extent of dark adaptation, and ab-
ormalities in color vision, on the other. All of
hese patients were less than 65 yr old and had nor-
al ocular findings. Controls consisted of 25 sub-
jects with no evidence of liver disease. Curves for
ean values of immediate and 30-min dark adaptation
nd of anomalies in color vision were correlated with
he severity of the liver disease and were signifi-
antly lower than mean values obtained on controls.
ecause of their poor pupillary response to changes
n light intensity, 34 of these 75 patients with
hronic liver disease could not drive a car. Errors
n color vision occurred over the entire color spec-
rum. Total vitamin A, vitamin A ester, and vitamin
alcohol (retinol) levels were determined on sera
rom 13 patients with cirrhosis and 10 controls before
nd after p.o. administration of 300,000 IU of vita-
in A. Before administration of the vitamin, the levels of all vitamin A fractions were significantly higher in controls than in cirrhotics. Peak levels, reached 4.5 hr after administration of a single dose of vitamin A, were significantly lower in patients with severe cirrhosis than in controls. While retinol accounted for almost all of the vitamin A present initially, both retinol and the ester fraction contributed equally to peak levels. No matter whether a single 300,000 IU dose of vitamin A was given or 30,000 IU/day, divided into 2 doses/day, was administered for 3 weeks, no improvement was observed in dark adaptation, pupillary response, or color vision. Curves plotted from mean values for immediate adaptation to darkness appeared to be higher among patients with chronic liver disease only on the 2nd day after administration of a single 300,000 IU dose of vitamin A. Thus, it could not be demonstrated that vitamin A had any therapeutic effect on dark adaptation or color vision in patients with chronic liver disease.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

7150 UREA-CYCLE ENZYMES IN ALCOHOLIC HEPATITIS. *(E.)* Maier, K. P.; Volk, B.; Hoppe-Seyler, G.; Gerok, W. (Dept. Intern. Med., Univ. Freiburg, Germany). *Eur. J. Clin. Invest.* 4(3):193-195, 1974.

Activities of enzymes in the Krebs-Henseleit cycle in alcoholic hepatitis were measured in liver biopsy samples to determine possible parameters of hepatocyte necrosis. Liver specimens from patients 3-4 months after acute hepatitis and from healthy subjects (both groups on a 100 g protein/day diet) were examined for DNA and protein content, and for enzyme activities of carbamyl phosphate synthetase, arginase, argininosuccinate lyase, ornithine-keto acid-transaminase, and ornithine-carbamyl phosphate transaminase. In alcoholic hepatitis, the protein content was significantly decreased while DNA content was slightly increased compared to normal liver values. Activities of carbamyl phosphate synthetase and of arginase were significantly decreased in diseased livers, but activity levels of the other 3 enzymes remained unchanged in both groups. Although alcoholic hepatitis and alcoholic liver cirrhosis cannot be differentiated enzymatically by the measurement of urea-cycle enzymes in liver tissue, the decrease in arginase and carbamyl phosphate synthetase can be demonstrated in the human liver prior to the histological signs of liver cirrhosis. Therefore, even though not typical for alcoholic origin only, arginase activity does represent a sensitive parameter of liver disease. The findings here show that controlled protein intake and standardized methods of enzyme extraction are prerequisites to accurate evaluation of enzyme activity in alcoholic hepatitis.

Cirrhosis

53 LIVER IN SICKLE DISEASE - A HISTOPATHOLOGICAL STUDY. *(E.)* Chaubey, B. S.; anchandani, G. B.; Grover, S. (Gov. Med. Coll. sp., Nagpur, India). *J. Assoc. Physicians India* (3):243-249, 1974.

ochemical and histological examinations were per- rmed on 27 patients (aged 2-31 yr) with homozygous ckle cell disease (SS) and 25 (aged 2-50 yr) with terozygous sickle cell disease (SA). Patients re from the central part of the Indian subconti- nt and all but 2 belonged to low socioeconomic oups. Measurements of serum protein, bilirubin, kaline phosphatase, SGPT, and SGOT showed minimal moderate liver dysfunction; anemia was mild. ver biopsies demonstrated dilation of sinusoids in (81.5%) of the SS group and in 8 (32%) of the SA oup. Kupffer cell hyperplasia was present in 17 2.9%) of the SS patients and 10 (40%) of the SA tients. There were 24 cases (88.8%) of parenchy- l damage in the SS group and 16 (64%) in the SA oup. Necrosis observed in 11 SS patients (40.7%) s paracentral and focal, with 3 cases showing anges suggestive of cirrhosis. Of the 4 cases 6%) of necrosis in the SA group, 2 showed minimal crosis and the other 2 had paracentral and focal crosis with cirrhosis. In the 5 biopsies sugges- ve of cirrhosis (2 in the SA group and 3 in the SS oup, 1 of which was associated with hepatoma), fi- osis was marked in the portal tracts but minimal ound sinusoidal elements and groups of degenerating d necrosed cells. The histology was consistent th multilobular cirrhosis. Since patients with history of viral hepatitis, chronic alcoholism, and gestion of hepatotoxic drugs were excluded from is study, the observed hepatic changes are due to ckle cell disease. The results suggest a progres- on to cirrhosis, with a transition from a monolo- ılar to a multilobular variety.

54 ABO BLOOD GROUPS, RHESUS NEGATIVITY, AND PRIMARY BILIARY CIRRHOSIS. *(E.)* Hamlyn, N.; Morris, J. S.; Sherlock, S. (Roy. Free Hosp., ndon, England). *Gut* 15(6):480-481, 1974.

ie distribution of blood groups and Rhesus negativ- ty in 91 British patients with primary biliary cir- iosis was compared with a sample of registered blood onors from various parts of the U.K. The incidence A, O, and B + AB groups in the 91 patients was ie same as in the controls. Similarly, regional ialysis for A and O in 4 areas of England showed ie same distribution in 96 patients with primary iliary cirrhosis as in the general populations of ie regions. Assuming a national frequency of 18%, ie incidence of Rhesus negativity (19) in the 91 atients with primary biliary cirrhosis was the same s in the general population. The results do not confirm previous reports of an excess of A group in primary biliary cirrhosis. If the disease has a genetic basis, blood group is invalid as a marker for susceptibility.

7155 FAMILIAL HEPATIC CIRRHOSIS IN INFANTS ASSOCIATED WITH ALPHA$_1$-ANTITRYPSIN SZ PHENOTYPE. *(E.)* Wilkinson, E. J.; Raab, K.; Browning, C. A.; Hosty, T. A. (Med. Coll. Wisconsin, Milwaukee). *J. Pediatr.* 85(2):159-164, 1974.

The fatal expression of α_1-antitrypsin deficiency is reported in 2 sibling neonates (a boy and a girl) with congenital hepatic cirrhosis and minimal respiratory distress syndrome. The boy died at age 75 hr and the girl at age 13 days. Both infants had a similar clinical pattern: intrauterine growth retardation, massive edema, oliguria, ascites, spider angiomas, icterus, and gastrointestinal bleeding. In each case, autopsy revealed a moderately dark green liver with numerous nodules and patent extrahepatic ducts. Extensive fibrosis, with moderate numbers of regenerative nodules, was evident. The degenerating hepatocytes were filled with tan acidophilic diastase-resistant bodies. The gallbladder was somewhat distended in each infant and contained mucoid bile. Lungs were poorly aerated and minimal hyaline formation and patchy atelectasis were seen in microscopic sections. Esophageal varices were present in the lowest 1/3 of the esophagus. Pi typing showed that the α_1-antitrypsin phenotype of the boy was SZ, a partial α_1-antitrypsin deficiency. Although Pi typing of the girl was not performed, the data suggest that she had a similar or identical deficiency. This is further indicated by the α_1-antitrypsin phenotype of the parents (mother FS and father MZ), as well as by the characteristic liver lesions. A marked decrease in α_1-antitrypsin concentration (42 mg/100 ml) in the cord serum of the boy, compared with normal levels (203 mg/100 ml), implies that α_1-antitrypsin does not cross the placental barrier. *In utero* diagnosis of the deficiency may be possible by study of the amniotic fluid.

7156 CIRRHOSIS AND DEATH AFTER JEJUNOILEAL SHUNT FOR OBESITY. *(E.)* Mangla, J. C.; Hoy, W.; Kim, Y.; Chopek, M. (Monroe Community Hosp., Rochester, N.Y.). *Am. J. Dig. Dis.* 19(8): 759-765, 1974.

A 41-yr-old woman who was just under 5 feet tall and weighed 260 pounds underwent a jejunoileal bypass in which 17 cm of jejunum were anastomosed (end-to-side) to the terminal 6 cm of ileum, and the bypassed 397 cm of small intestine were left as a blind loop. Although the patient had a history of heavy drinking, preoperative liver functions were all normal, with the exception of a slight increase in alkaline phosphatase, and the liver appeared normal on gross examination at surgery. The patient was later readmitted twice, 4 and 7 months after surgery, for diarrhea which responded to diet therapy. Liver function tests became progressively more abnormal and a liver biopsy, performed during the 3rd hospitalization, showed severe fatty metamorphosis but no evidence of hepatocellular necrosis or regenerative nodule formation. Since liver function tests improved and the patient gained weight with diet therapy, plans to reestablish bowel continuity were cancelled. On her final hospital admission, 11 months after surgery, the patient presented with weakness, gross muscle wasting, gross ascites, peripheral edema, and hepatomegaly. Liver function tests showed still further degeneration, but tests for hepatitis-associated antigen were repeatedly negative. Diarrhea (up to 4 liters/day) and hepatic coma followed tube and i.v. feedings, but the patient was a poor risk for reestablishing bowel continuity. Succeeding episodes of hepatic coma continued until the patient died from hepatic failure and the effects of starvation 25 months after the bypass operation. Autopsy showed cerebral atrophy, jaundice with ascites (2500 ml), splenomegaly, esophageal varices, a healing gastric ulcer, and generalized moniliasis. Patent cirrhotic changes were found at autopsy although the patient was definitely not taking alcohol during the last 3 months of life. Although the cause of liver changes after ileal bypass is unknown, it is suggested that hepatic toxicity of absorbed secondary bile salts, the absence of a vital lipotrophic factor due to malnutrition, or the blind loop syndrome may be involved.

7157 SEX, ASCITES AND ALCOHOLISM IN SURVIVAL OF PATIENTS WITH CIRRHOSIS: EFFECT OF PREDNISONE.

(E.) Tygstrup, N.; Juhl, E.; Winkel, P. (Rigshosp., Copenhagen, Denmark). *N. Engl. J. Med.* 291(6):271-273, 1974.

Follow-up studies were conducted on 512 patients with cirrhosis (240 women and 272 men, mean age 59.45 yr) seen over a 7-yr period. Of these patients, 260 were treated with prednisone (15-20 mg/day initially, followed by 10 mg/day) and 252 received placebos. Survival data for prednisone-treated patients and controls were analyzed according to the criteria of sex, ascites, and alcoholism. Survival of the steroid-treated patients was significantly greater than that of controls. Female sex was the most positive single factor determining the effect of prednisone on survival, and ascites was the most negative factor. A significant alcohol consumption (50 g or more/day for more than 5 yr) tended to be a negative factor, but was too closely linked with male sex to be analyzed separately. In female patients with compensated, nonalcoholic cirrhosis, prednisone treatment increased the 6-yr survival by 1/2 to 2/3. Prednisone appeared to be ineffective in the treatment of compensated, nonalcoholic male patients. The results also indicate a possibly harmful effect of prednisone in patients with decompensated or alcoholic cirrhosis. However, the dosage and duration of therapy in the present study may not give the optimum balance between therapeutic and side effects.

7158 PSEUDO-ACUTE ABDOMEN IN CIRRHOSIS.

(Ger. Pedreira, J. D.; Villalonga, C.; Martinez-Vasquez, J. M.; Guardia, J.; Tornos, J.; Bacardi, R. (Munic. Hosp. Soc. Welfare, Free Univ., Barcelona, Spain). *Munchen. Med. Wochenschr.* 116(25):1253-1256 1974.

Case reports are presented for 8 patients (7 men and 1 woman, aged 41-60 yr) with cirrhosis who developed acute abdomen as a result of infectious peritonitis. These patients consisted of 3 with nodular cirrhosis 2 with alcoholic cirrhosis, and 3 with biliary cirrhosis. In most cases, the history of cirrhosis date back 1 yr or less, and peritonitis was the first complication in 6 of these 8 patients. None of the patients had undergone paracentesis before. In all cases, ascites fluid was cloudy, but many cultures of blood and ascites fluid were negative, probably because the patients had received antibiotics before they were hospitalized. *Escherichia coli* was isolated from ascites fluid in 4 cases, pneumococci in 2, and streptococci in 1. Five patients died 2 hr to 14 days after hospitalization. The cause of death was septic shock in 4 cases and hepatic encephalopathy in 1. Three patients responded to systemic an local antibiotics and paracentesis.

7159 PRIMARY BILIARY CIRRHOSIS AND SCLERODERMA.

(Fr.) Geffroy, Y.; Colin, R.; Hemet, J.; Galmiche, J. P.; Guillard, J.; Hecketsweiler, P. (Charles Nicolle Hosp., Rouen, France). *Med. Chir. Dig.* 2(5):281-286, 1973.

A 71-yr-old woman, hospitalized with jaundice, had a long history of arthralgias involving the hands, feet, and vertebrae; typical Raynaud's syndrome; telangiectasia; and sclerodactylia confirmed by a skin biopsy. The patient had suffered from asthenia and recurrences of jaundice which were not accompanied by abdominal pain, fever, or pruritis since an episode of jaundice 8.5 yr before. This episode of jaundice was compatible with viral hepatitis and regressed spontaneously after 1 month. Cholestasis and conjugated hyperbilirubinemia had been diagnosed during another recurrence 7 months prior to hospitalization. Although the jaundice regressed, the patient lost 10 kg, cholestasis persisted, and serum alkaline phosphatase values increased to 700 IU. After hospitalization a diagnosis of primary biliary cirrhosis was established on the basis of chronic intrahepatic cholestasis and the presence of high titers of antimitochondrial antibodies. However, n cirrhosis was detected at laparoscopy or in a punch liver biopsy. Other immunological abnormalities included positive rheumatoid rosettes and increased immunoglobulin levels, particularly the IgM fractio An incomplete autopsy, performed after the patient died of a stroke and before treatment with corticosteroids or immunosuppressants had been begun, confirmed the diagnosis of primary biliary cirrhosis. Periportal inflammatory cirrhosis was associated with lesions of the biliary canaliculi, some of whic were completely atrophied. Islets of epithelioid cells surrounding the canaliculi might represent a local immune reaction of the cellular type toward terial derived from the canaliculi as a result of gression which could be of viral, toxic, or un-own origin. Only 11 other cases of primary biliary rrhosis associated with scleroderma have been re-rted in the literature.

50 STUDIES OF SERUM AND URINARY BILE ACIDS IN PATIENTS WITH DECOMPENSATED CIRRHOSIS. *er.)* Wildgrube, H. J.; Dittmann, K.; Erb, W. (Ctr. tern. Med., Univ. Frankfurt/Main, Germany). *Verh. sch. Ges. Inn. Med.* 79:953-954, 1973.

ter separation into free, conjugated, and sulfated actions on Sephadex columns, bile acids in blood d serum from 30 patients with decompensated cirrho-s were analyzed by gas chromatography. The re-lts showed great variations in serum and urinary le acid concentrations and confirmed that there s a correlation between the cholanic acid concen-ations and the extent of cholestasis. Serum bili-oin and bile acid concentrations were only slight- above the upper normal range in a patient with stnecrotic cirrhosis and abnormal liver function sts (increased transaminase activities, normal kaline phosphatase activity, and decreased cholin-terase and albumin levels), while serum bile acids re significantly increased in another patient with oical signs of cholestasis. In cirrhotics with evidence of cholestasis, small quantities of bile ids were excreted in the urine and sulfate esters re present only in trace quantities in the blood d urine. When cirrhosis was accompanied by choles-sis, bile acids increased significantly. Sulfate ters of bile acids accounted for 10-20% of the in-ease in the serum and for 25-50% of the increase urine. In jaundiced patients cholic acid was the jor constituent of the nonsulfated fraction and enodeoxycholic acid the major constituent of the lfated fraction, suggesting that the damaged liver s retained its ability to produce sulfate esters. patients with liver metastases, as much as 60% of inary bile acids were present as sulfate esters, ile this fraction constituted only 2% of serum e acids.

1 INCORPORATION OF 4-^{14}C-CHOLESTEROL IN CHOLESTEROL ESTER FRACTIONS OF HDL, LDL, VLDL IN CIRRHOSIS. *(Ger.)* Weizel, A. (Med. n., Univ. Heidelberg, Germany). *Verh. Dtsch. . Inn. Med.* 78:1365-1367, 1972.

study esterified cholesterol in serum lipopro-n fractions, 2 patients with compensated cirrho- were injected i.v. with 6-30 μCi of 4-^{14}C-lesterol, either in an alcoholic solution or er preincubation with serum. Blood samples were en at regular intervals after injection, and very density (VLDL), low density (LDL), and high sity (HDL) lipoprotein fractions were isolated ultracentrifugation. Esterified and free choles-ol were then separated by thin-layer chromatog-hy, and the specific activities of these frac-ns were determined. In a 65-yr-old man with rhosis and total cholesterol levels of 100-120 100 ml, the ratio of esterified to free choles-ol was decreased to 1.0 (normal values are around 2.2), and esterified cholesterol concentrations were particularly low in the LDL and HDL fractions. However, incorporation of 4-^{14}C-cholesterol into the lipoproteins followed the same pattern as in subjects with normal serum cholesterol levels. The same results were obtained on a 60-yr-old male cirrhotic with total cholesterol levels of 140 mg/100 ml. It is concluded that there are no qualitative or quantitative changes in cholesterol esterification mechanisms due to the decrease in esterified cholesterol levels in cirrhosis.

7162 EFFECT OF AZATHIOPRINE ON CIRRHOSIS IN MAN AND EXPERIMENTAL ANIMALS. *(Ger.)* Perings, E.; Brunner, G.; Creutzfeldt, W. (Med. Clin., Univ. Gottingen, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:946-948, 1973.

Animal studies were performed to account for the deleterious effect of azathioprine on patients with cirrhosis. Of 21 cirrhotics treated with this drug, 10 died during or shortly after discontinuation of azathioprine treatment. Cirrhosis was induced in 122 male Wistar rats by carbon tetrachloride (CCl_4) treatment (0.75 ml s.c. twice a week for 4 months) and in 30 rats by a choline-deficient diet administered for 8 months. Rats were then divided into 4 groups. Group I was given 26 CCl_4 injections, followed by azathioprine (25 mg/kg/day p.o. through an esophageal tube) for 24 days and 6 more CCl_4 injections. Group II received 35 CCl_4 injections followed by a 10 day interval and then the above dose of azathiprine for 4 weeks. Rats with cirrhosis induced by a choline-deficient diet were given the above dose of azathioprine for 4 weeks. About 50% of the azathioprine-treated animals in all 4 groups died within 4 weeks, while only 3 of 62 untreated cirrhotic controls died during the same period. In group II, serum transaminase activities were higher in azathioprine-treated rats than in controls, and histological findings generally correlated with serum transaminase levels, both in animals given CCl_4 and those fed the choline-deficient diet. To rule out the possibility that azathioprine has a toxic effect on the normal liver, 20 normal rats were given 25 mg/kg/day azathioprine p.o. for 90 days. No increases occurred in serum transaminase values, and no liver changes were found in these rats. Although the high mortality in cirrhotics treated with azathioprine cannot be explained, it may be that azathioprine is metabolized at a slower rate by the cirrhotic liver. Cirrhosis is considered to be a contraindication for azathioprine therapy.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

7179 THE ORGANIC MATRIX OF GALLSTONES. *(E.)* Sutor, D. J.; Wooley, S. E. (Dept. Chem., Univ. Coll., London, England). *Gut* 15(6):487-491, 1974.

Cholesterol gallstones were dissolved in chloroform and sodium chenodeoxycholate solutions, while calcium carbonate and calcium phosphate stones were dissolved in hydrochloric acid and tetrasodium or di-odium salts of ethylenediaminetetraacetic acid. n all cases dissolution left an amorphous and gel-ike matrix. The matrix from cholesterol stones could e colorless but was usually orange, yellow, or brown hile that from calcium carbonate and calcium phos-hate stones was almost invariably black or dark rown. X-ray diffraction photographs and figure nalysis suggested that these pigments were also or-anic and amorphous. The amount of matrix present nd its structure varied with the texture of the rystalline material. Irrespective of their compo-ition, laminated stone areas yielded a compact ma-rix of the same shape as the original material, hile areas of loose crystalline material gave small ieces of noncohesive matrix. Only large cholesterol tones, which usually radiated from the stone nucleus, ad no associated matrix. The close structural rela-ion between crystalline material and matrix in gall-tones indicates that their deposition is in some way onnected. The relative roles played by each in the ucleation and growth of a stone cannot usually be educed; but in radiating cholesterol crystals with-ut observable matrix, crystal growth occurred inde-endently of the substance. Small pieces of choles-erol gallstones dissolved *in vivo* by chenodeoxycholic cid could remain in the gallbladder and act as a idus for further stone formation if the bile is in supersaturated state. Such growth will occur at a uch lower level of supersaturation than required for omogeneous nucleation and stone formation is there-ore more likely to recur.

7180 SURGICAL INDICATIONS IN PATIENTS WITH SILENT GALLSTONES. *(E.)* Sato, T.; Matsushiro, T. (Tohoku Univ. Sch. Med., Sendai, Japan). *Am. J. Surg.* 128(3):368-375, 1974.

Characteristics of patients with silent and symptomatic cholecystolithiasis were studied. Silent gallstones were found in 32 of 784 surgically treated patients with cholelithiasis and were composed of cholesterol in 24 cases and pure pigment in 8. Only 2.8% of 217 patients younger than 49 yr had silent cholesterol stones compared with 7.3% of 109 patients aged 50-59 yr, 7.4% of 81 patients aged 60-69 yr, and 20% of 20 patients > 70 yr. This age-related trend was not observed with pure pigment stones. In 152 subjects with gallstones proved at autopsy, the incidence of silent gallstones (type unspecified) was also high among aged patients. Patients with silent stones and those with cholecystolithiasis at the intermediate stage did not differ with respect to number of stones, presence of bacteria in bile, or histological changes in the gallbladder wall in relation to composition of stones. Inflammatory changes in the wall of the gallbladder were most prominent with cholesterol stones followed by pure pigment stones, with comparatively slight changes in patients with calcium bilirubinate stones. Onset of symptoms in patients with silent gallstones was more sudden in the older age groups and was frequently accompanied by acute cholecystitis. Operative mortality was 8.8% for patients hospitalized with acute disease compared with 0.2% for patients with disease at the intermediate stage. The incidence of cancer of the gallbladder associated with gallstones increased with age, occurring in 3.8% of men and 9.3% of women older than 60 yr. The data indicate that up to age 30 patients with cholecystolithiasis should be treated conservatively. Conversely, early cholecystectomy is recommended for patients aged 40-70 yr and even for older patients who are still active.

7181 USE OF C-TERMINAL OCTAPEPTIDE OF CHOLECYSTOKININ IN CHOLECYSTOGRAPHY. *(E.)* Levant, J. A.; Sturdevant, R. A. L. (VA Wadsworth Hosp. Ctr., Los Angeles, Calif.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 121(2):380-383, 1974.

The effect of the C-terminal octapeptide of cholecystokinin (20 ng/kg, i.v.) on gallbladder contraction was investigated in 30 patients (29 men and 1 woman, mean age 48.6 yr) undergoing oral cholecystography. The common bile duct was visualized in 14 (47%) patients after this administration. Mean peak decrease in gallbladder size, measured at 5, 10, and 15 min after injection, was 48% with a range of 10-100%. Peaks occurred at 5 min in 5 patients, at 10 min in 12, and at 15 min in 13; the mean decreases in size for the 3 time periods were not significantly different. In 4 patients, decrease in gallbladder size was less than 40%. An additional i.v. injection of 40 ng/kg cholecystokinin octapeptide in these 4 patients produced further contraction in only 1 patient. Common bile duct visualization was not increased by a 2nd injection of 40 ng/kg. The side effects in 25 patients were mild (nausea in 15 patients; abdominal cramps, 9; and abdominal pressure or other discomfort, 9), transient, and well tolerated. No evidence of toxicity was found on physical examination or laboratory evaluation 24 hr after administration. This study provides evidence that the cholecystokinin octapeptide is safe and effective for use as a gallbladder contracting agent in humans. Although the diagnostic value of gallbladder contraction is uncertain, possible advantages include visualization of gallstones not seen without contraction, visualization of bile ducts and choledocholithiasis, reproduction of spontaneous pain of biliary dyskinesia, correlation of the pain with roentgenographic features, and possible prediction of future cholelithiasis.

7182 THE ROLE OF BILE ACIDS IN THE PATHOGENESIS OF POSTVAGOTOMY DIARRHOEA. *(E.)* Allan, J. G.; Gerskowitch, V. P.; Russell, R. I. (Roy. Infirm., Glasgow, Scotland). *Br. J. Surg.* 61(7): 516-518, 1974.

Fecal bile excretion was analyzed over a 5-day period in 7 patients (5 women and 2 men, 30-59 yr old) with continuous, severe diarrhea after vagotomy and drainage surgery 3-8 yr previously, in 7 volunteer normal controls, and in 7 nondiarrheic patients after vagotomy and drainage operation 2 yr previously. The total bile acid secretion in the feces was significantly increased in the patients with diarrhea (2538 mg/day) compared with normal controls (799 mg/day). Although no significant difference in total fecal bile acid excretion was observed between the 2 groups of patients with vagotomy, a significant increase in the fecal excretion of chenodeoxycholic acid was found in the patients with diarrhea (460 mg/day) as opposed to the other 2 groups (170 in patients without diarrhea and 82 in controls. There was no statistically significant difference in the excretion of cholic acid, deoxycholic acid, or lithocholic acid between the postvagotomy diarrhea group and the controls. Histology study showed normal villous structure in the jejunum in all patients with diarrhea. It is suggested that the increase in chenodeoxycholic acid excretion may be a factor in the pathogenesis of postvagotomy diarrhea.

7183 ALTERATIONS IN THE CONCENTRATION OF CHOLESTEROL IN BILE AFTER ADMINISTRATION OF HUMAN GROWTH HORMONE.

(E.) Poley, J. R.; Smith, J. D.; Thompson, J. B.; Seely, J. R. (Children's Mem. Hosp., Oklahoma City, Okla.). *Pediatr. Res.* 8(7):710-714, 1974.

The concentration and molar percentage of cholesterol, bile acids, and phospholipids were measured over an 18-month period in 3 neonates with growth hormone deficiency and in 1 control neonate with constitutionally short stature but normal growth hormone secretion. Investigations were made before and after 0.3, 4, and 12 months of therapy with exogenous human growth hormone (3 U/week). Two hormone-deficient patients showed accelerated height velocities of 1.3 and 0.2 cm/yr to 10.5 and 3.0 cm, resp., after 4 months of treatment. During this time, the lithogenic index (ratio between cholesterol concentration in a given bile sample and the maximal cholesterol concentration that could be dissolved in the sample) rose from 1.00 and 0.93 initially to 1.66 and 1.10, resp., indicating a progressive increase in bile concentration, since normal lithogenic index is 1.00. The 3rd patient also showed some growth acceleration, but his bile did not become oversaturated with cholesterol. After 0.3 month of growth hormone treatment, the control subject exhibited a height velocity increase from 2.8 to 8.0 cm/yr; his bile was excessively saturated with cholesterol levels as indicated by a rise in the lithogenic index from 0.10 to 2.94, the highest yet reported for humans. However, this abnormal response to human growth hormone was not sustained, and bile composition later returned to normal. These findings suggest that human growth hormone influences hepatobiliary cholesterol dynamics associated with bile production.

7184 LONG-TERM RESULTS OF HEPATIC PORTOENTEROSTOMY FOR BILIARY ATRESIA: SPECIAL REFERENCE TO POSTOPERATIVE PORTAL HYPERTENSION.

(E.) Miyata, M.; Satani, M.; Ueda, T.; Okamoto, E. (Osaka Univ. Med. Sch., Japan). *Surgery* 76(2):234-237, 1974.

Over a 4-yr period, 51 infants (aged 1-5 months) with congenital biliary atresia underwent Roux-en-Y portoenterostomy. Jaundice disappeared completely in only 15, all of whom were under age 4 months at time of surgery. Ten patients died within 1 month postoperatively due to complications. Four patients in whom jaundice disappeared died from portal hypertension within 18-41 months of surgery. Portal hypertension was also the cause of death in all but 6 of the 22 jaundiced patients who died 2-18 months postoperatively. While portal hypertension was only apparent postoperatively in the patients in whom jaundice disappeared, it was evident preoperatively in those with persistent jaundice. Among patients in whom jaundice disappeared, 5 of a total of 7 with portal hypertension (71.4%) developed retrograde cholangitis. This suggests a close relation between retrograde cholangitis and postoperative portal hypertension.

7185 SUCCESSFUL RESECTION OF CARCINOMA OF THE COMMON HEPATIC DUCT AT ITS SUPERIOR BIFURCATION.

(E.) Camprodon, R.; Salva, J. A.; Jornet, J.; Guerrero, J. A. (Francisco Franco Munic. Sanit., Barcelona, Spain). *Am. J. Surg.* 128(3):433-435, 1974.

A 61-yr-old man presented with progressive jaundice, asthenia and anorexia, and a weight loss of 10 kg in 1 month. Physical examination showed marked hepatomegaly without tenderness and a nonpalpable gallbladder. At surgery, the liver was enlarged, the gallbladder flaccid, and the common bile duct small in circumference. Preoperative diagnosis of carcinoma of the common hepatic duct at its superior bifurcation was established by retrograde cholangiography of the common bile duct and the intrahepatic vessels by transhepatic puncture. Resection of both hepatic ducts was performed at the level of the umbilical notch, and continuity of the biliary-digestive system was reestablished by hepaticojejunostomy with a Roux-en-Y loop. Postoperatively, the pigmentation of the skin returned to normal and the patient gained 8 kg within 3 months. His condition remains satisfactory 16 months postoperatively.

7186 COMPARATIVE STUDY OF VARIOUS TECHNIQUES FOR X-RAY CONTRASTING OF THE BILIARY TRACT.

(Rus.) Lisitsyn, K. M.; Severova, N. S.; Vorotnikova, R. P. (Central Milit. Hosp., Moscow). *Vestn. Khir.* 111(12):32-34, 1974.

The purpose of the study was to compare diagnostic values of i.v. drip cholegraphy with alternative methods of contrasting the biliary tract. In 3 yr, 890 contrast X-rays were taken of the biliary tract of 758 patients. There were 700 peroral cholecystographies, 58 i.v. and 132 drip-i.v. cholegraphies. The latter involved i.v. drip injection of 150-200 ml of 5% glucose solution with 40-60 ml of 20% bilignost (1 ml/kg) heated to 37 C mixed with insulin (0.3 - 0.5 U/kg) and s.c. injection of 0.5 ml of 1% morphine hydrochloride. The technique produced clear contrasting of the biliary tract in 88% of the patients and was twice as efficient as the conventional i.v. choleography. This technique is recommended for studies of the biliary tract after cholecystography or when other methods fail to yield a contrasting image. Intravenous cholegraphy by drip infusion provides a sharp image of the biliary tract. The absence of the gallbladder contrasting is a sign of the bladder obstruction and an indication for surgery. Counterindications are kidney deficiencies with oliguria.

37 CLINICAL AND MORPHOLOGICAL CHARACTERISTICS OF BILIARY ATRESIA AND CONGENITAL HEPATI-

. *(Rus.)* Rudenskaia, I. N.; Gavriushov, V. V.;
kovskaia, A. I. (I. V. Rusakov Clin. Hosp.
liatrics No. 2, Moscow, USSR). *Pediatriia* (1):37-
1973.

hough clinical findings were similar in 36 child-
(23 boys and 13 girls) with biliary atresia and
children (16 boys and 11 girls) with congenital
atitis, patients with congenital hepatitis had
nificantly lower birth weights; slower weight
ns; and a higher incidence of developmental de-
ts, associated diseases, and bleeding. While
ndice developed a few days after birth in all
ldren with biliary atresia and in 17 of those with
genital hepatitis, 10 in the latter group did not
elop jaundice until age 2 weeks to 7 months.
le jaundice was persistent in patients with bil-
y atresia, it regressed in 8 patients with con-
ital hepatitis and was recurrent in 3 others.
iary anomalies were successfully corrected by
gery in only 3 of the 24 operated patients with
iary atresia. The remaining patients in this
up had anomalies which could not be corrected
gically. Biopsies performed on 30 of 36 children
h biliary atresia all showed marked periolobular
rosis and some with biliary cirrhosis had actively
liferating bile canaliculi, pronounced cholesta-
, and bile thrombi and bile "lakes". Other com-
findings were infiltrates of lymphocytes and
tiocytes in the stroma and parenchyma, parenchy-
dystrophy, and giant cell transformation. Biop-
es performed on 20 of the 27 children with congeni-
hepatitis showed subacute giant cell cholestatic
atitis (13 cases), congenital giant cell hepa-
is progressing to cirrhosis (6 cases), and acute
al hepatic necrosis (1 case). During the first
months of life no differences were found between
lesterol and bilirubin levels and SGOT and SGPT
ivities in children with biliary atresia and those
h congenital hepatitis. Liver failure was respons-
le for all of the 23 deaths that occurred among
ldren with biliary atresia and for 13 of the 17
aths among children with congenital hepatitis. Al-
ough it is not always possible to establish a dif-
rential diagnosis between these 2 diseases by liver
opsies and laparoscopy, laparotomy is not recom-
nded because of the serious consequences that can
sult in patients with congenital hepatitis and
cause the hepatitis may regress in some of these
ildren. The complement fixation test for toxo-
asmosis was positive in only 1 child with biliary
resia, and cytomegalic inclusion virus was iso-
ted from 3 children with biliary atresia and 1
th congenital hepatitis.

38 ADENOMATOUS POLYP OF THE HEPATIC DUCT WITH OBSTRUCTIVE JAUNDICE: ONE CASE REPORT.

or.) Biccas, Jr., L.; Cabas, R. V.; Goncalves, C.
(Clin. Hosp., Fed. Univ. Espirito Santos, Vitoria,
azil). *Arq. Gastroenterol. (Sao Paulo)* 11(3):173-
7, 1974.

A 42-yr-old woman with a history of 3 episodes of jaundice which regressed spontaneously presented with pain in the right hypochondrium and epigastric region, jaundice, and pruritis. An oral cholecystogram, taken 1 yr previously, showed a nonfunctioning gallbladder. A provisional diagnosis of choledocholithiasis was established. At laparotomy the common hepatic duct was dilated right above its junction with the cystic duct. Palpation revealed the presence of a soft, mobile tumor, the consistency of which differed from that of gallstones or malignant neoplasms. The common bile duct was normal and the gallbladder was edematous, had thickened walls, but contained no calculi. When the common bile duct was dissected, a pedunculate tumor was found in the common hepatic duct with its base in the right hepatic duct and its distal extremity blocking the proximal common bile duct. After complete removal of the tumor, a choledochostomy was performed, followed by insertion of a T-drain and a cholecystectomy. Histological examination of the tumor disclosed that it was an adenomatous polyp. Apparently the mobility of the polyp accounts for the intermittent nature of the jaundice in this patient. Obstruction of the common bile duct was intermittent and was reduced when the patient was in dorsal decubitus. Postoperative cholangiograms were normal, confirming that only a single polyp was present.

7189 BILE LIPOPROTEIN CONCENTRATIONS IN CHRONIC BILIARY DISEASE IN CHILDREN. *(Ukr.)*

Donde, S. M. (Kiev Sci. Res. Inst. Pediatr. Obstet. Gynecol., USSR). *Pediatr. Akush. Ginekol.* 36(2):18-19, 1974.

Lipoprotein concentrations were determined by paper electrophoresis on gallbladder and hepatic bile from 144 children (99 girls and 45 boys, aged 5-14 yr) with acute biliary disease. Of these patients, 71% had bacterial angiocholecystitis, 13% had giardiasis, and 16% had biliary dyskinesia. Controls consisted of 22 normal children of the same ages. Most of the patients had associated infections; 40% had helminthiasis; stomach disorders were diagnosed in 48%, including 27% with chronic gastritis; and liver function tests were abnormal in 48 of these 144 patients. Lipoprotein concentrations in both gallbladder and hepatic bile samples were significantly lower in patients with bacterial angiocholecystitis and giardiasis than in controls. Biliary lipoprotein concentrations did not differ appreciably between patients with biliary dyskinesia and controls. A relation was found between the extent to which bile lipoprotein concentrations were decreased and the duration of the disease: lipoprotein concentrations remained essentially unchanged in children with histories of 1 yr or less, while concentrations were significantly decreased in children with histories of longer than 1 yr. This can probably be explained by involvement of the liver and impairment of its bile-secreting function in biliary disease of long duration. A correlation was found between the extent to which lipoproteins were decreased and the severity of biliary inflammation. However, bile lipoprotein concentrations were also decreased in children who had large amounts of mucus and many epithelial cells and WBC in their duodenal contents and in children with 5-10 WBC/field in their bile. While lipoprotein concentrations tended to normalize in gallbladder bile after treatment, their concentrations in hepatic bile remained decreased despite regression of clinical symptoms. It is likely that 3-4 weeks of treatment in the hospital is not enough to restore normal bile secretion by the liver in chronic biliary disease, and patients should be treated on an outpatient basis. Determination of bile lipoprotein concentrations is recommended as a valuable test that reflects hepatobiliary function.

7190 RECURRENT CHOLESTASIS INDUCED BY ORAL CONTRACEPTIVES IN PRIMARY SCLEROSING CHOLANGITIS. *(Ger.)* Hartmann, W.; Goebell, H.; Beneke, G.; Ruhle, K. H. (Ctr. Intern. Med. Pediatr., Univ. Ulm, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:964-967, 1973.

A 24-yr-old woman with a history of colic-like pain in the upper right abdomen, associated with transient jaundice and fevers up to 40 C, developed jaundice, pruritis, and a fever after ingestion of an oral contraceptive. Although the drug was discontinued, jaundice recurred after 9 months, and the patient noted that she developed a fever every month about 10 days before each menstrual period. A trial of Eugynon (composition not specified) induced persistent cholestasis and hepatosplenomegaly. Increases occurred in the erythrocyte sedimentation rate; bilirubin, γ-globulin, and serum copper levels; and alkaline phosphatase and leucine aminopeptidase activities. These abnormalities persisted for about 1 yr. Primary biliary cirrhosis was ruled out by a failure to find antimitochondrial antibody. Laparotomy showed thickening and stenosis of the common and intrahepatic bile ducts with perilobular fibrosis and intimal proliferation in branches of the portal vein. Granulomas in the hepatoduodenal ligament were strikingly similar to rheumatoid nodules found in rheumatoid arthritis. Postoperative recurrence of fever and jaundice was successfully treated with fluocortolone (10 mg/day). These findings suggest that primary sclerosing cholangitis may only be a manifestation of some systemic collagen disease. The cyclical course of cholestasis might be attributed to swelling of collagen connective tissue in the affected bile ducts caused directly by sex hormones.

7191 LONG-TERM AND VERY LONG-TERM FUNCTIONAL RESULTS OF CHOLEDOCHODUODENOSTOMY. *(Fr.)* Mallet-Guy, P. (no affil.). *Chirurgie* 99(8):505-511, 1973.

Of 563 side-to-side choledochoduodenostomies performed over a 20-yr period, 56 were performed for neoplastic obstructions. The remaining 507 patient with non-neoplastic lesions underwent 316 operation and 191 reoperations for post-cholecystectomy syndrome. Mortality during the first 60 days after surgery averaged 13% and increased with the age of the patients. Of these 507 patients, 336 were followed for 1-24 yr after surgery. Primary operation and reoperations for recurrent lithiasis were successful in 89-92% of the patients, in contrast to 76.7-78.5% of patients with postcholecystectomy syndrome due to other causes. Clinical and radiologically confirmed recurrences developed after several years in 39 patients (11.6% of the patients followe for more than 1 yr). In 25 cases failure resulted from partial or complete obliteration of the mouth of the anastomosis; this complication was more comm in reoperated patients. Another cause of failure was overlooked stones (7 cases). Since symptoms occurred only at long intervals 3 patients did not undergo further surgery, and symptoms subsided afte extraction of an abscessed tooth in another patient Thus, only 3 of the 336 patients followed (0.9%) could be classified as true failures. These findin indicate that ascending cholangitis does not occur very often after choledochoduodenostomy.

7192 CARCINOMA OF THE GALLBLADDER AND EXTRAHEP TIC BILIARY TREE. *(E.)* Johnson, F. W.; Gilsdorf, R. B. (VA Hosp., Minneapolis, Minn.). *Am Surgeon* 40(8):456-461, 1974.

GENERAL

47 THE PROGNOSTIC VALUE OF THE CUTANEOUS DELAYED HYPERSENSITIVITY RESPONSE TO 2,4-
NITROCHLOROBENZENE IN GASTROINTESTINAL CANCERS. .) Bone, G.; Appleton, D. R.; Venables, C. W. ept. Surg., Univ. Newcastle upon Tyne, England). . *J. Cancer* 29(5):403-406, 1974.

e relation between the initial delayed hypersensi-
vity reaction to 1-chloro-2,4-dinitrobenzene,
llowing sensitization, in patients with gastroin-
stinal cancers and their subsequent survival has
en studied. The 70 patients (38 males and 32 fe-
les, aged 36-81 yr) were sensitized by the appli-
tion of 4000 μg of 1-chloro-2,4-dinitrobenzene
ssolved in acetone and applied to a 3 cm^2 area of
in on the volar aspect of the forearm. At least
days after sensitization, 4 patch test squares
ch impregnated with a different strength of 1-
loro-2,4-dinitrobenzene in acetone were applied to
e opposite forearm. The patients were then graded
cording to sensitivity as follows: I, sensitive
200 μg only; II, sensitive to 200 and 100 μg;
I, sensitive to 200, 100 and 40 μg; and IV, sensi-
ve to all strengths of 1-chloro-2,4-dinitrobenzene
sted. The cancer patients were divided almost
ually among the 4 groups with no significant dif-
rence between the proportions in each group. All
t one of the control patients showed a delayed
persensitivity reaction for 1-chloro-2,4-dinitro-
nzene and the majority were graded III. Studies of
rvivors showed a striking correlation between
eir relative anergy and their subsequent progress.
e prognosses for group IV responders was the most
vorable with a progressive decline showing dimi-
shed initial response. A clear linear relation
ists between the strength of the delayed hypersen-
tivity response to an exogenous allergen (1-chloro-
4-dinitrobenzene) and the short-term prognosis in
tients with gastrointestinal cancers. Since pa-
ents who were anergic had only a 20% chance of
rviving for 6 months, it is questionable whether
dical surgery is justified in such patients un-
ss something can be done to reverse their "aner-
c" state. Routine use of the delayed hypersensi-
vity test in gastrointestinal cancer patients may
useful in clinical assessment and lead to changes
management.

7248 AN IMMUNOADSORBENT PROCESS OF REMOVING HEPATITIS ANTIGEN FROM BLOOD AND PLASMA. *(E.)* Charm, S. E.; Wong, B. L. (Tufts Univ. Sch. Med., Boston Mass.). *Biotechnol. Bioeng.* 14(5):593-607, 1974.

An immunoadsorbent process had been devised for removing serum hepatitis antigen (HAA), from blood, blood plasma, and plasma products. The immunoadsorbent complexes specifically with HAA. The complex is then removed from the plasma by filtration. Ammonium hydroxide (0.23 M) is used to dissociate the complex. The immunoadsorbent is regenerated for further processing, while the purified HAA by-product may be used to produce more antibody in animals. The rate of complexing is such that HAA is reduced one log cycle each 2 hr. Since available tests can only detect HAA to about 10^9 particles/ml, it is proposed that HAA negative plasma and plasma products can be processed to reduce HAA to a probability of less than one HAA particle/plasma pool. A gibbon injected with infectious commerical Factor IX that was subjected to the immunoadsorbent process showed no sign of infection after 8 months. However, 14 weeks after injection with unprocessed Factor IX, the gibbon showed signs of infection. This is considered presumptive evidence of infection by the unprocessed Factor IX. More than 80% of the Factor IX was recovered from the immunoadsorbent process.

Parasitology

14 METRONIDAZOLE AND AMEBIASIS. *(E.)*
Everett, E. D. (Fitzsimons Army Med. Ctr.,
nver, Colo.). *Am. J. Dig. Dis.* 19(7):626-636, 1974.

sponse to metronidazole therapy was analyzed in 15
tients with colonic amebiasis (12 with acute amebic
sentery and 3 with coexisting liver abscesses) and
12 patients with amebic liver abscesses treated
thout aspiration. The 15 patients (10 men and 5
men, aged 18-49 yr) with amebic colitis received 750
metronidazole 3 times/day for 5-25 days. Diarrhea
ased in all dysenteric patients within 24-120 hr,
d fever was reduced in 10 patients in 24-72 hr. Af-
r one course of treatment 2 patients developed clin-
al and parasitological relapses. One became clini-
lly well after a 2nd 10-day course of metronidazole
d had negative stools at 6 weeks. The other patient
s retreated for 5 days with a good clinical response
t had positive stools 10 days later. She was cured
th tetracycline, emetine, and diiodohydroxyquin.
e asymptomatic patient with cysts of *Entamoeba his-*
lytica responded to 5 days of treatment; stools were
gative 2 months after treatment. The 12 patients
ales, aged 20-39 yr) with hepatic amebiasis were al-
treated with 750 mg metronidazole 3 times/day for
26 days, without aspiration. All patients were fe-
ile on admission. Duration of fever and pain, if
esent, was 24-240 hr after institution of therapy.
ither duration of illness nor size of the abscess
d predictable correlation with response to therapy
healing rate of the abscess. All patients were
inically well at the last follow-up examination.
4 patients with abscesses, there was evidence of
lmonary involvement prior to therapy; in 1 of these,
apparent progression of the disease occurred with
rupture of the abscess into a bronchus, but the pa-
ent responded to reinstitution of metronidazole.
de effects of the drug were minimal in both groups.
e data indicate that 750 mg metronidazole 3 times/day
r 5 days is adequate therapy for amebic dysentery.
en aspiration is not part of treatment for hepatic
ebiasis, the same dosage for 10 days should be ade-
ate; if necessary, therapy can be prolonged without
gnificant toxicity.

GENERAL

Regional Enteritis

7330 INCIDENCE OF GRANULOMA IN CROHN'S DISEASE. *(E.)* Assarsson, N.; Raf, L. (Serafimer Hosp., Stockholm, Sweden). *Acta Chir. Scand.* 140(3): 249-251, 1974.

Reports on 287 surgical cases of Crohn's disease were analyzed for the occurrence of tuberculoid granuloma and giant cells in resected material. Granuloma and/or giant cells were noted in 63% of the patients. The incidence of such changes was significantly higher in children and young people than in other age groups. Of 99 patients 19 yr old or younger, 84% had positive findings compared with 45% of 54 patients aged 40-79 yr. The site of the intestinal changes did not differ significantly between groups with and without granuloma. Extensive changes involving more than 50 cm of the intestine were found in 34% of patients with specific changes compared with 25% of those without such changes. The left colon was involved in 27% of patients with granuloma and in 18% of those without specific changes. The two groups did not differ with regard to course and prognosis of the disease. Reoperation had been performed on 28% of patients with specific changes and on 25% of those without.

7331 CROHN'S DISEASE OF THE DUODENUM (TRANSMURAL DUODENITIS). *(Fr.)* Farmer, R. G.; Hawk, Jr., W. A.; Turnbull, Jr., R. B. (Cleveland Clin. Fdn., Ohio). *Ann. Gastroenterol. Hepatol. (Paris)* 9(3):249-254, 1973.

Of 1150 patients treated for Crohn's disease, 14 (7 males and 7 females, aged 13-55 yr) had symptoms which primarily involved the duodenum. Of these 14 patients, 8 had a history of enteritis or Crohn's disease of the colon and 6 presented with duodenal symptoms. Clinical symptoms were suggestive of upper intestinal obstruction in 8 cases and of atypical duodenal ulcers in 4; 2 patients had both types of symptoms. Clinical and radiological evidence of obstruction of the 1st and 2nd parts of the duodenum were found in 10 of the 14 patients. Complications consisted of cutaneous fistulas (3 cases) and perirectal abscesses (3 cases). Surgery for duodenal lesions was performed on 11 of the 14 patients: for obstruction in 7, for ulcer in 3, and for both indications in 1 case. At surgery all 11 patients were also found to have lesions of the ileum and 3, lesio of the jejunum; 1 later developed colitis. Gastroenterostomies designed to bypass inflamed and/or obstructed parts of the duodenum were performed on 9 patients. One patient underwent a duodenojejunostom and another an antrectomy combined with gastrojejuno stomy. No vagotomies were performed. All of these patients are alive after 6 months to 5 yr. Little o no symptoms of duodenal involvement have been obser in 12 patients. One patient who had been treated conservatively had to undergo duodenal bypass becau of a relapse, and another patient developed gastrointestinal bleeding but surgery proved unnecessary. These findings indicate that Crohn's disease of the duodenum is more common than previously recognized, and patients may present with duodenal symptoms.

7332 CROHN'S DISEASE OF THE STOMACH, ILEUM AND COLON. *(E.)* Kim, S. K.; Bowers, Jr., W. E.; Walstead, P. M. (Harlan Appalachian Reg. Hosp., Harlan, Ky.). *J. Ky. Med. Assoc.* 72(6):322-324, 1974.

7333 MILIARY CROHN'S DISEASE. *(E.)* Daum, F.; Boley, S. J.; Cohen, M. I. (Montefiore Ho Bronx, N.Y.). *Gastroenterology* 67(3):527-530, 1974

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

7334 THE ULTRASTRUCTURE OF THE SMALL INTESTINAL MUCOSA IN THE DEVELOPING HUMAN FETUS. *(E.)*

Varkonyi, T.; Gergely, G.; Varro, V. (Univ. Med. Sch., Szeged, Hungary). *Scand. J. Gastroenterol.* 9(5):495-500, 1974.

The submicroscopic structure of the jejunum was examined in 3 groups of human fetuses corresponding to 6-8 weeks, 8-10 weeks, and 10-12 weeks gestation. The tissues were fixed in 2.5% glutaraldehyde, washed with phosphate buffer, and postfixed in 1% osmium tetraoxide. The material was dehydrated in graded alcohol series and embedded in Durcupan. Preparations were evaluated with a JEM 100 B electron microscope. In the 6-week-old embryo, the epithelium of the small intestinal mucosa is formed by a single layer of epithelial cells arranged radially toward the lumen. There are no microvilli except for some cytoplasmic protuberances; nuclei, mitochondria, rough endoplasmic reticulum are seen in the cytoplasm. In the 8th to 10th week of gestation the epithelial cells differentiate and appear as a cylindrical cell layer. Microvilli begin to appear as well as a massive amount of glycogen granules in the cytoplasm. The cells lie on a basal membrane at this period. In the 10th to 12th week period, the cells begin to resemble enterocytes without forming villi structures. At the surface, the so-called glycocalyx structure appears. The cytoplasm contains all the organelles that are seen in the earlier period of gestation except that they are more developed in this period. Enterochromaffin cells and some goblet cells are observed only in the 12th week of gestation. The results show that the morphological basis of absorption, the small intestinal barrier, develops in the first 3 months of pregnancy. The mucosa at this stage of development is very similar to that seen in advanced stages of absorptive disturbances in adult mucosa e.g., in the sprue syndrome. Further investigations may lead to an understanding of the mechanism of mucosal damage in human malabsorption.

7335 DEVELOPMENT OF STRIATED MUSCLE FIBRES IN THE HUMAN OESOPHAGUS. *(E.)*

Jit, I.; (Inst. Med. Educ. Res., Chandigarh, India). *Indian J. Med. Res.* 62(6):838-844, 1974.

Development of the striated muscle fibers in the muscular coat of the human esophagus was studied in 12 closely graded embryos between 11.5 and 158 mm C.R. stages. The 38 mm C.R. stage was the first stage to show striations appearing in the upper 1/3 of the esophagus in a few inner fibers of the longitudinal coat and adjacent fibers of the circular coat. The inner fibers of the longitudinal coat and the outer fibers of the circular coat showed striations at the 42 mm stage in the upper 1/3 of the esophagus. The middle 1/3 of the esophagus demonstrated striations in a few inner fibers of the longitudinal muscle coat at the 68 mm stage. There was no further progress in muscular striations from the 75 to 99 mm C.R. stages. All of the fibers of the longitudinal coat and most of the circular coat except the innermost layers of the upper 1/3 of the esophagus and some fibers of both coats of the middle 1/3 had striations at the 110 mm C.R. stage. At the latter stage and the 158 mm stage, there was still no evidence of striations in the lower 1/3 of the esophagus. In the development of striated muscles, the coarse myofibrils show granules which remain united by the intervening portions of the myofibril. The granules assume a quadrilateral shape and the fiber assumes a striated appearance in the direction of the long axis of the fiber. The breadth of these granules increases and splitting occurs in the longitudinal direction--the muscle fiber then appears cross striated. The results do not support the suggestion that pharyngeal musculature spreads onto the esophagus.

7336 MORPHOLOGY AND CELL PROLIFERATION OF SUBEPITHELIAL FIBROBLASTS IN ADULT MOUSE JEJUNUM. II. RADIOAUTOGRAPHIC STUDIES. *(E.)*

Marsh, M. N.; Trier, J. S. (Harvard Med. Sch., Boston, Mass.). *Gastroenterology* 67(4):636-645, 1974.

Cell proliferation and migration of subepithelial fibroblasts in the jejunal mucosa of adult Charles River mice was studied by high-resolution light-microscopic radioautography. Animals received 6 i.p. injections of ^{3}H-thymidine (25 μC; specific activity, 6.1 μC/mM) at hourly intervals. In the first 12 hr after exposure to isotope, labeled subepithelial fibroblasts were found only in the crypt region, indicating that only pericryptal fibroblasts synthesized DNA and proliferated. By 24 hr, labeled fibroblasts were seen in the proximal and middle 1/2 of the villi, and by 36 hr, labeled fibroblasts appeared in the distal 1/3 of the villi. Thus, there appeared to be migration of subepithelial fibroblasts from the pericryptal lamina through the subepithelial tissues of the villi toward the villus tips. In contrast, endothelial cells were labeled at all levels of the mucosa 6 hr after exposure to ^{3}H-thymidine, indicating that these cells are capable of proliferation regardless of their location within the mucosa. Fibroblasts and epithelial cells migrated in synchrony to the base of the villi; thereafter, labeled fibroblasts appeared to migrate more rapidly to the tips of the villi than did labeled epithelial cells. Radiation damage, observed in crypt epithelial cells, may have interfered with epithelial cell proliferation and migration.

7337 PATTERN OF OSMIUM DEPOSITION IN THE PARIETAL CELLS OF THE STOMACH. *(E.)*

Winborn, W. B.; Seelig, Jr., L. L. (Univ. Texas Health Sci. Ctr., San Antonio). *J. Cell Biol.* 63:99-108, 1974.

7338 THE SURGICAL ANATOMY OF THE PORTA HEPATIS. *(E.)*

McArthur, M. S.; Hiatt, J.; Bastounis, E. A. (Univ. California Sch. Med., Los Angeles). *J. Surg. Res.* 17(2):111-113, 1974.

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

7339 THE INTESTINAL CELL SURFACE: SOME PROPERTIES OF NORMAL, UNDIFFERENTIATED, AND MALIGNANT CELLS. *(E.)* Isselbacher, K. J. (Harvard Med. Sch., Boston, Mass.). *Ann. Intern. Med.* 81(5):681-686, 1974.

See also, 7348, 7383, 7461, 7619, 7625, 7729, 7730, 7819, 7876.

ABSORPTION–EXCRETION–TRANSPORT

7340 THE INTESTINAL UNSTIRRED LAYER: ITS SURFACE AREA AND EFFECT ON ACTIVE TRANSPORT KINETICS. *(E.)* Wilson, F. A.; Dietschy, J. M. (Univ. Texas Hlth. Sci. Ctr., Dallas). *Biochim. Biophys. Acta* 363(1):112-126, 1974.

The effective surface area of the unstirred layer in the rat jejunum and ileum was calculated, along with the effect of this diffusion barrier, in relation to the active transport of several sugars, amino acids, and bile acids. The surface area varied from 1.02-14.24 cm^2/100 mg dry weight of rat intestine. These values were determined by analyzing 1) the effect of stirring on the kinetics of passive permeation and active transport into the intestinal mucosa and 2) the maximal rates of passive uptake of compounds whose rates of absorption are limited by the unstirred water layer. The values of the surface area were much lower than those found for the microvillus membrane in the jejunum (1226 cm^2/100 mg) and in the ileum (696 cm^2/100 mg). This indicated that the effective surface area of the rate-limiting membrane for such highly permeable solutes as long-chain fatty acids is from 1/100 to 1/200 of the actual anatomical surface area. The kinetics of active transport were examined for D-glucose, D-galactose, L-serine, taurocholate, and taurodeoxycholate during absorption into the ileal mucosal cell, with the thickness of the diffusion barrier being varied by altering the rate of stirring of the bulk incubation solution. The stirring appeared to have relatively little effect on the apparent maximal achievable transport rate but did significantly lower the apparent Michaelis constant for the transport carrier. The relative reduction of the apparent Michaelis constant caused by stirring was roughly proportional to the apparent value for the maximal transport rate for a particular probe molecule. Stirring decreased the apparent Michaelis constant by a factor of 3.2 for L-serine, 3.4 for D-galactose, 2.8 for D-glucose, 2.0 for taurocholate, and 1.6 for taurodeoxycholate. Hence, the presence of the unstirred layer appears to introduce major artifacts into the determination of the Michaelis constant and maximal transport rate values for the active transport process.

7341 INTESTINAL TRANSPORT OF TRITIATED FOLIC ACID (^{3}H-PGA) IN THE EVERTED GUT SAC OF DIFFERENT AGED RATS. *(E.)* Bhanthumnavin, K.; Wright, J. R.; Halsted, C. H. (NICHD Gerontol. Res. Ctr., Baltimore City Hosp., Md.). *Johns Hopkins Med. J.* 135(3):152-160, 1974.

The intestinal transport of tritiated folic acid (^{3}H-PGA) was measured in everted gut sacs prepared from male Wistar rats at ages 1.5 months, 6 months, 12 months, and 24 months to examine the possibility that decreased intestinal absorption of folate could contribute to the folate deficiency of aging. In sacs prepared from 6-week-old rats and incubated in the presence of glucose, a saturable transport system was observed, with K_t of 2.7 μM and V_{max} of 4.4 nM/g/30 min. The omission of glucose from the incubation medium resulted in deterioration of the sacs when incubated beyond 5 min. No significant change in the jejunal uptake of ^{3}H-PGA was observed in the gut sacs of the rats ranging in age from 1.5 to 24 months.

7342 INTESTINAL ABSORPTION OF D-XYLOSE AND FOLIC ACID MEASURED BY A PERFUSION TECHNIQUE IN PATAS MONKEYS (Erythrocebus patas). *(E.)* Gyr, K.; Wolf, R. H.; Felsenfeld, O. (Tulane Univ. Delta Reg. Primate Res. Ctr., Covington, La.). *Am. J. Vet. Res.* 35(11):1441-1444, 1974.

Absorption activity of the small intestine in 16 patas monkeys (*Erythrocebus patas*), 8 male and 8 female, was determined by perfusion of a 20-cm intestinal segment with fluid containing D-xylose (25 mg/ml) and folic acid (25 mg/ml). Phenol red was used as nonabsorbable marker for the correction of the dilution or concentration of the solute. Two 15-min samples of the intestinal fluid were collected after a 30-min equilibration period. An average of 15.89% D-xylose and 22.25% folic acid was absorbed. Significant correlation existed between folic acid absorption and D-xylose absorption which is consistent with reported observations that the 2 substances are absorbed in the same area; that is, mainly in the upper part of the small intestine. The results are comparable to data available from studies in man, except that less D-xylose is absorbed in the patas monkey than in man.

7343 THE EFFECT OF GLYCINE-CONJUGATED BILE ACIDS ON NET TRANSPORT AND POTENTIAL DIFFERENCE ACROSS ISOLATED RAT JEJUNUM AND ILEUM. *(E.)* Wingate, D. L. (London Hosp. Med. Coll., England). *J. Physiol. (Lond.)* 242(1):189-207, 1974.

The effects of conjugated bile acids on net transport across *in vitro* jejunum and ileum segments from male Sprague-Dawley rats were compared in an attempt to determine if the inhibition of absorption might be reproducible *in vitro*. Five mM glycodeoxycholate and glycochenodeoxycholate inhibited net fluid transport across isolated rat jejunum and ileum. Five mM glycocholate did not affect jejunal segments, but did arrest fluid transport across ileal segments. Inhibition of fluid transport was accompanied by some diminution of mucosal glucose uptake, but translocation of glucose to the serosal surface of jejunal segments persisted in the presence of dihydroxy conjugated bile acids. Inhibition of fluid transport was accompanied by a marked fall in the glucose-stimulated transmural electropotential difference, within 5 min of mucosal exposure to the bile acids. The results suggest that inhibition of intestinal fluid transport is reproducible *in vitro*, and that the inhibition is not associated with increased permeability of the mucosa, but may be associated with altered permeability of the mucosal pole of the enterocyte.

7344 METHIONINE ACCUMULATION IN VILLI ISOLATED FROM MATURING RAT INTESTINE.

(E.) Fondacaro, J. D.; Nathan, P.; Wright, W. E. (Univ. Cincinnati Coll. Med., Ohio). *J. Physiol. (Lond.)* 241(3):751-760, 1974.

The absorption of methionine by mucosal cells of the rat small intestine was characterized and compared with the absorption patterns in different areas of the small intestine from 15- and 30-day-old Wistar rats, preweaned and postweaned, resp., using a new *in vitro* method, the villus technique. This technique permits the evaluation of the mucosal absorptive cells separated from the relatively non-transporting muscle and connective tissue components. Mucosal cells incubated in methionine below 1.0 mM concentration had about the same transport capacity in preweaned and postweaned rats. Although this observation was true for both the duodenum and jejunum, there was significantly greater methionine transport in the ileum from preweaned than from postweaned rats at initial concentrations below 1.0 mM. With initial methionine concentration greater than 1.0 mM, duodenal and jejunal villi from preweaned animals transported methionine better than villi from older animals. With increasing initial concentration of methionine, unknown physiological changes occurred during maturation due to slower transport rates into villi of mature duodenal and jejunal tissues than into similar tissue from preweaned rats. The results indicate that the absorbing mucosal cells from the duodenum, jejunum and ileum have an equal capacity for methionine accumulation following maturation.

7345 REGIONAL DIFFERENCES IN COMPARTMENTAL DISTRIBUTION OF PALMITATE IN INTESTINE.

(E.) Mishkin, S.; Wener, R.; Yalovsky, M.; Kessler, J. I. (McGill Univ. Clin., Montreal, Canada). *Am. J. Physiol.* 227(4):771-777, 1974.

The uptake and compartmental distribution of micellar palmitic acid by different regions of hamster small intestine were investigated by incubating paired everted sacs of female golden hamsters (each small intestine was divided into 9 segments, 3 cm in length). The incubation time was 10 min at 37 C under 95% O_2-5% CO_2, in 10 ml of micellar incubation medium that contained 10 μM [1-^{14}C] palmitic acid (0.05 C/μM), 10 μM monoolein, 100 μM taurodeoxycholate, and 100 μM glucose made up in 0.15 M Krebs-Ringer buffer. Subsequently, the sacs underwent serial rinsing in ice-cold Krebs-Ringer buffer and 2.5% albumin. Uptake of radiopalmitate by the proximal segments was greater, but the distal segments released a larger proportion of the radiopalmitate uptake into Krebs-Ringer buffer and into albumin. While the proportion of radiopalmitate in the free fatty acid fraction of the tissue after rinsing remained quite constant regardless of location, the radioactivity in the esterified fatty acid fraction of the proximal segment was 5-fold greater. The fraction of the uptake released by rinsing was inversely related to the fraction of esterified radiopalmitate. The marked regional differences in compartmental distribution of radiopalmitate could be entirely accounted for by differences in esterification.

7346 GLUCOSE ACCUMULATION BY RAT SMALL INTESTINE DURING ABSORPTION IN VIVO.

(E.) Leese, H. (Dept. Biol., Univ. York, Heslington, England). *Nature (Lond.)* 251(5475):512-513, 1974.

The accumulation of glucose to give a small intestinal tissue concentration higher than that in the bathing fluid has been observed in a wide variety of *in vitro* preparations; here, it is extended to an *in vivo* situation. About 20 cm of jejunum from male Wistar rats under ether anesthesia was exposed, and the lumen rinsed with 10 ml ice cold 0.9% NaCl. The segment was cannulated, and the lumen perfused *in situ* with Krebs-Ringer bicarbonate medium. During perfusion, the gut was replaced inside the body wall, and the animal maintained continuously under ether. After 5 min perfusion, glucose was added to the luminal circuit, and the perfusion continued for a further 10 min. When the initial concentration of glucose in the lumen was 5.55 mM, there was an approximately 2-fold uphill gradient of glucose from lumen to plasma. In this situation, the gut wall concentrated the glucose to a level almost 1.5 times that in the plasma, and over 3 times that in the lumen, so that a downhill movement of glucose could take place from the tissue into the blood. In the complete absence of glucose in the lumen, and in the presence of phlorizin, a substantial amount of glucose was present in the gut wall, probably in the mucosa. This may be explained by a backward movement of glucose from the plasma to the epithelial cells. The results suggest that gut glucose concentrations during absorption are influenced more by the concentration of sugar in the plasma rather than that in the lumen.

7347 INHIBITION OF ACTIVE TRANSPORT BY OUABAIN IN THE CANINE STOMACH.

(E.) Kuo, Y. M.; Bowen, J. C.; Smith, J. W.; Sernka, T. J.; Jacobson, E. D.; Shanbour, L. L. (Univ. Texas Med. Sch., Houston). *Proc. Soc. Exp. Biol. Med.* 147(1):144-147, 1974.

The effects of ouabain on active transport and the electrical properties of an *in vivo* canine stomach preparation in 6 fasted mongrel dogs were explored and the findings compared with flux measurements in an *in vitro* canine stomach preparation in 12 dogs. Ouabain (50 μg/kg) decreased the potential difference (PD) of histamine-stimulated canine gastric mucosa *in vivo*. Calculated electrical resistance (PD/I) was not decreased, and the rate of acid secretion was unaltered by ouabain. These findings support the inference that ouabain inhibits active chloride transport to diminish PD. This inference was verified by the *in vitro* experiments in which ouabain inhibited the net flux of chloride in the acid-bathed mucosal segment.

7348 EFFECTS OF VITAMIN D_3 ON DUODENAL ABSORPTIVE CELLS OF CHICKS. AN ELECTRON MICROSCOPIC STUDY.

(E.) Jande, S. S.; Brewer, L. M. (Fac. Med., Univ. Ottawa, Ontario, Canada). *Z. Anat. Entwicklungsgesch.* 144(3):249-265, 1974.

Duodenal epithelial cells of 30 White Leghorn chicks were studied at the electron microscopic level to determine the effects of vitamin D on the cells directly involved in calcium absorption in the time scale of its known biochemical and physiological effects. The chicks were placed on a rachitogenic test diet 2 days after hatching. After 4 weeks, 1/2 the chicks were injected i.m. with 500 IU of vitamin D_3. Three chicks of similar age, raised on a normal diet, were used as controls. The depletion of vitamin D led to a decrease in the length of microvilli of the brush border, in the number of apical pits and vesicles, in the size of the Golgi complex, the amount of rough endoplasmic reticulum and in the relative number of secondary lysosomes, while the repletion of vitamin D caused a subsequent increase. Previously described physiological effects of vitamin D on calcium absorption, when coupled with these new morphological observations, suggest a possible mechanism for calcium absorption by the duodenal cells.

7349 INCREASED PHENOLSULFONPHTHALEIN ABSORPTION FOLLOWING DISRUPTION OF THE GASTRIC MUCOSAL BARRIER BY UREA.

(E.) Bowen, J. C.; Fischer, R. P.; Ritchie, Jr., W. P. (Walter Reed Army Inst. Res., Washington, D.C.). *Proc. Soc. Exp. Biol. Med.* 147(1): 280-283, 1974.

The absorption of phenolsulfonphthalein (PSP) in canine Heidenhain pouches before and after the topical application of 4 M urea was determined. Associated changes in the net fluxes of H_2O, H^+, K^+, and Cl^- and the net and bidirectional fluxes of Na^+ were also assayed to document disruption of the mucosal barrier. PSP absorption before urea instillation averaged 0.13 μM/30 min/100 cm^2 mucosal area. Following urea, an average of 0.63 μM/30 min/100 cm^2 mucosal area was absorbed. Associated ionic and water flux rates demonstrated significantly increased back diffusion of H^+ and influx of Na^+, K^+, and water into the lumen. The observation of over a 4-fold increase in PSP absorption after urea instillation indicated that mucosal permeability was increased; increased effective pore area may be responsible. It was also suggested that this observation provides evidence that the observed alterations in ionic fluxes are, in fact, the result of altered mucosal permeability. It was concluded that PSP should not be used as a volume marker in studies in which the integrity of the gastric mucosal barrier is altered.

7350 COMPUTER MODELING OF NONSTEADY STATE SODIUM KINETICS IN LIVER.

(E.) Smith, G. A.; Llaurado, J. G. (Med. Coll. Wisconsin, Milwaukee). *IEEE Trans. Biomed. Eng.* 21(6):433-443, 1974.

A procedure for constructing a computer model of nonsteady state sodium kinetics in liver was based on obtaining 1) continuous tracer outflow records from liver fragments *in vivo* of male white rats injected i.p. with 1 mC ^{24}Na, and 2) an independent tracee (the material of interest) prototype record by flame photometry from liver fragments incubated in a Krebs medium at 37 C, in the course of a comparable *in vitro* period. In the computer modeling procedure, 1st, a 2 compartment model with time varying parameter characteristics was built with the aid of the SAAM computer program; and 2nd, the approach was extended to a symmetric linked juxtaposition of 2 systems, 1 for tracer and 1 for tracee, each consisting of 3 compartments. From the transport rate constants obtained, Na relative compartment sizes and percent of extracellular (EC) fluid volume were calculated. Results for the 3 compartment model, qualitatively consistent with published physiological details, are in agreement with previously reported data. Significantly, the values found for the Na transport rate constants, Na relative compartment sizes and percent of EC fluid volume are not affected by fluctuations intrinsic to auxiliary indicators of EC space, but are based solely on measurements of Na.

7351 CATION TRANSPORT IN THE LIVER IN HEMORRHAGIC SHOCK.

(E.) Sayeed, M. M.; Wurth, M. A.; Chaudry, I. H.; Baue, A. E. (Washington Univ. Sch. Med., St. Louis, Mo.). *Circ. Shock* 1(3):195-208, 1974.

Cation transport capability was measured in liver slices of male Holtzman rats bled to mean arterial blood pressure of 40 mm Hg. This pressure was maintained for 1/2, 1, or 2 hr to reproduce conditions of early, intermediate, and late shock, resp. *In vitro* sodium-potassium transport was inhibited in early, intermediate, and late shock and was accompanied by a loss of cell volume regulation. Sodium and water contents increased and tissue adenosine nucleotides decreased with shock. The decreases in ATP, ATP:ADP ratio, and the energy charge values in intermediate and in late shock probably were not of such a magnitude to indicate complete loss of the *in vitro* sodium-potassium transport. The impairment of cation transport with shock can thus be related to a factor other than energy availability. *In vitro* cation transport was restored to normal with reinfusion of all shed blood and Ringer's lactate in early shock but not in intermediate shock.

7352 UPTAKE AND TRANSPORT OF MACROMOLECULES BY THE INTESTINE. POSSIBLE ROLE IN CLINICAL DISORDERS.

MOTILITY

7363 ACUTE EXPERIMENTS ON NEUROEFFECTOR FUNCTION IN CANINE ESOPHAGEAL ACHALASIA. *(E.)* Gray, G. W. (Coll. Vet. Med., Univ. Minnesota, St. Paul). *Am. J. Vet. Res.* 35(8):1075-1081, 1974.

Acute experiments were performed on 5 normal dogs and 3 dogs with spontaneous achalasia, defined as megaesophagus with esophageal retention of ingested material and with intermittent regurgitation. Regardless of the voltage and frequency of cervical vagal stimulation *in vivo*, far weaker intraesophageal pressure responses were produced in dogs with achalasia than in controls. The major esophageal motor responses were the twitch and tetanic type characteristic of striated muscle. An additional slow motor response was present and prominent in the thoracic part of the esophagus of dogs with achalasia; this may have been due to smooth muscle contraction. The thoracic cavity was opened to permit direct visualization of esophageal response to maximal vagal stimulation. Dogs with achalasia responded only with isolated concentric rings of weak contraction, while controls showed marked tetanic contraction of the entire esophagus. *In vitro* studies were performed on 2 nerve-muscle preparations from the thoracic esophagus of each dog. These results support the view that the twitch and tetanic responses observed both *in vivo* and *in vitro* are due to striated muscle contraction, while transient slow and sustained contractions induced by acetylcholine (10^{-7} to 10^{-5} g/ml) *in vitro* and by vagal stimulation *in vivo* are due to smooth muscle in the esophageal wall. Since vagal influence on the heart rate was abnormal and/or deficient in all dogs with achalasia, it is suggested that the esophageal contractile defect in these dogs is neural, rather than muscular, in nature.

7364 THE RELATIVE SIGNIFICANCE OF ELECTRICAL SPIKE POTENTIALS AND INTRALUMINAL PRESSURE WAVES AS QUANTITATIVE INDICATORS OF MOTILITY. *(E.)* Oigaard, A.; Dorph, S. (Rigshosp. Copenhagen, Denmark). *Am. J. Dig. Dis.* 19(9):797-803, 1974.

The relative significance of electrical spike potentials and intraluminal pressure waves as quantitative indicators of motility was studied from 60 recordings of the intestine of normal volunteers and patients. Short sequences (20-50 sec) of synchronized cinefluorography were used to correlate the pressure and spike potential parameters with visible intestinal activity. Spike potentials corresponding to pressure waves of low amplitude and short duration nearly always started before the onset of the pressure wave, with the interval ranging from less than 1 sec to a maximum of 2 sec. The onset of pressure waves of greater amplitude and longer duration most often preceded the onset of the corresponding spike potential. For larger, complex pressure waves the tendency was even more marked, with a maximum interval of 12 sec. No corresponding pressure wave was observed for 20% of the spike potentials, though spike potentials of more than 3 sec pulse duration and greater than 370 microvolts in amplitude always had a pressure correlate. Pressure waves without a corresponding spike potential occurred in 3% of the recordings. Computer correlations for 1000 corresponding pairs of spike potentials and pressures in terms of all possible combinations of amplitude and duration were statistically significant. Combinations that included amplitude of spike potentials, however, showed a correlation coefficient below 0.33 in contrast to all other combinations ranging between 0.6 and 0.8. Spike potential duration correlated reasonably well with the degree of visible activity, though the spike amplitude showed a great range in variation. A fair correlation was also found between the degree of visible activity and pressure wave characteristics. Spike potentials without corresponding pressure waves apparently represented weak muscular activity which was not reflected in the intraluminal pressure. Pressure waves without an electrical counterpart probably reflected activity in adjacent bowel segments.

7365 EFFECTS OF PENTAGASTRIN ON ELECTRICAL ACTIVITY OF SMALL INTESTINE OF THE DOG.

(E.) Weisbrodt, N. W.; Copeland, E. M.; Kearley, R. W.; Moore, E. P.; Johnson, L. R. (Univ. Texas Med. Sch., Houston). *Am. J. Physiol.* 227(2):425-429, 1974.

The effect of pentagastrin on the myoelectric activity of the small intestine was determined in 3 conscious dogs (1 male and 2 female). The animals were implanted with electrodes spaced 25 cm apart along the entire length of the small intestine, and a cannula was placed in the most dependent portion of the stomach. Recordings were made with dogs in the fasted and fed states and during infusion of pentagastrin in doses of 1 or 2 μg/kg/hr. In the fasted periods and during pentagastrin infusion, the cannula was open to divert gastric secretions from the duodenum. Two distinct patterns of myoelectric activity were recorded: one typical of the fasted state (the interdigestive myoelectric complex) and one typical of the fed state. Infusion of pentagastrin into the fasted animals changed the pattern of myoelectric activity from that of a fasted condition to that of a fed condition, indicating that the change in small intestinal myoelectric activity caused by the ingestion of food may in part be due to the release and action of gastrin. The fact that the spike potential pattern induced by pentagastrin was not as regular as in the fed state indicated that there were probably factors in addition to gastrin which were responsible for the conversion of the fasted to the fed state.

7366 INTESTINAL TRANSMURAL ELECTRICAL PROPERTIES: EFFECTS OF CONJUGATED BILE SALT IN VITRO.

(E.) Wall, M. J.; Baker, R. D. (Med. Coll. Wisconsin, Milwaukee). *Am. J. Physiol.* 227(2):499-506, 1974.

The effects of conjugated bile salt on the *in vitro* transmural electrical properties of flat sheets of rat small intestine were studied by monitoring the transmural electrical potential difference, short-circuit current (expressed as the voltage drop across a 100 ohm resistor in series with the intestine), and areal specific resistance before and after the addition of taurocholate to the incubation medium. Segments of intestine were excised from either the upper jejunum (just below the ligament of Treitz) or terminal ileum and placed in Krebs-Henseleit bicarbonate solution. An abrupt increase in transmural potential difference and short-circuit current occurred in terminal ileal sheets immediately upon exposure to 10 mM taurocholate; no effect was observed in the upper jejunal sheets. Areal specific resistance was reduced by taurocholate in both ileal and jejunal preparations. The effect of the bile salt on transmural potential difference and short-circuit current depended on oxidative metabolism, whereas the effect on areal specific resistance did not. Unidirectional influx of taurocholate into ileal epithelium was also found to require oxidative metabolism. Short-circuit current and areal specific resistance effects were maximal at a taurocholate concentration of 5 mM, and the critical micellar concentration for taurocholate was about 6 mM for the experimental conditions. The electrical effects observed thus appeared to be caused by bile salt monomers and not by micelles. The hypothesis that active transport of taurocholate and electrogenicity are mediated by a common set of receptors are not supported by the data. Concentration dependency of electrogenicity differs from that for unidirectional influx of taurocholate into ileal epithelium.

7367 QUANTITATIVE ANALYSIS OF MOTILITY RECORDING IN THE HUMAN SMALL INTESTINE. *(E.)*

Oigaard, A.; Dorph, S. (Rigshosp., Copenhagen, Denmark). *Am. J. Dig. Dis.* 19(9):804-810, 1974.

Simultaneous measurements of intraluminal pressure and electrical-action potentials (spike potentials) in the human duodenum were recorded for 100 persons (patients without upper gastrointestinal-tract diseases and normal volunteers). Motor-active drugs (pyridostigmine bromide or metoclopramide) were administered i.v. after a fasting period of 20 min, and recording was continued for another 20-30 min. Consecutive 50-sec periods (corresponding to one page of graph paper) of combined pressure and electrical tracings were classified in a stepwise scale of increasing activity according to the frequency of spike potentials in combination with frequency, duration, and amplitude of the corresponding pressure waves. Synchronized cinefluorography was used to correlate the tracing with visible intestinal activity. The duration of spike potentials appeared to correlate well with the duration and amplitude of pressure waves. At high levels of intestinal contraction, pressure was found to be more informative. Vigorous contractions associated with gross segmentation or propulsion were almost always observed during pressure elevations of medium or maximum size, while corresponding spike potentials did not necessarily indicate a high level of activity. Spike potentials observed in the absence of pressure waves and probably representing weak contractions in a small segment of the circular muscle coat of the small intestine appeared to confirm the greater sensitivity of the electrical parameter for motility measurements. A combination of the pressure and electrical parameters is proposed for clinical motility studies.

SECRETION AND METABOLISM

Stomach

7414 NEONATAL SECRETION OF GASTRIN AND GLUCAGON. *(E.)* Rogers, I. M.; Davidson, D. C.; Lawrence, J.; Ardill, J.; Buchanan, K. D. (Stobhill Hosp., Glasgow, Scotland). *Arch. Dis. Child.* 49(10):796-801, 1974.

Plasma gastrin and glucagon levels were estimated in mothers after labor, and in their babies at birth and on the 4th day of life. The newly born baby appears to secrete gastrin independently and the plasma levels are higher on the 4th day of life. The cord gastrin level is lower when labor is induced or augmented by the i.v. infusion of oxytocin. These results do not exclude the possibility that gastrin is transferred from mother to baby during a spontaneous labor. Such a maternal component of cord gastrin may be responsible for neonatal gastric hyperacidity. The mean cord glucagon level is higher than the maternal level at birth and the 4th day level is higher than the cord level. The C-terminal reactive glucagon-like immunoreactivity in the cord blood is lower when oxytocin has been used during labor. Maternal or placental transfer of C-terminal reactive glucagon-like immunoreactivity during labor to the spontaneously born baby is one possible explanation of this finding. The raised glucagon levels on the 4th day may explain why there is low gastric acidity at this time despite the gastrin level being higher than at birth. No relation could be deduced between the C-terminal reactive glucagon-like immunoreactivity, i.e. pancreatic glucagon level, and the blood glucose level either at birth or on the 4th day of life.

7415 THE BINDING OF GASTRIC MUCOPROTEIN TO CELLS IN TISSUE CULTURE AND THE INHIBITION OF CELL ADHESION. *(E.)* Allen, A.; Minnikin, S. M. (Dept. Biochem., Univ. Newcastle upon Tyne, England). *Biochem. Soc. Trans.* 2(4):633-635, 1974.

The binding of blood-group-active mucoprotein from pig gastric mucoprotein to baby hamster kidney cells in tissue culture and the inhibition of baby hamster kidney cell adhesion by different mucoprotein preparations was studied with radioactive labeling techniques. Radioiodine-labeled mucoprotein at 37 C in Tris-buffered saline was used to incubate monolayers of baby hamster kidney cells harvested by mild trypsinization; after incubation, the cells were separated from the unbound radioiodine-labeled mucoprotein by centrifugation for subsequent counting for radioactivity. The gastric radioiodine-labeled mucoprotein bound rapidly to the cells, approaching maximum binding after the first 5 min of incubation. Saturation occurred when the amount of labeled mucoprotein added to a constant number of cells was increased, with the amount bound 10^6 cells being 93 μg mucoprotein. Alternatively, if more cells were added to a constant amount of labeled mucoprotein, the amount of protein bound increased; however, a maximum binding was reached when 7.2% of the total labeled mucoprotein was bound, and no further reaction occurred with the addition of more cells. This suggested that only a small proportion of the radioiodine-labeled mucoprotein molecules have the necessary structural requirements for binding to the kidney cells. The binding of the mucoprotein to the kidney cells was dependent on the presence of divalent cations in the medium and was considerably decreased at 4 C. Different preparations of gastric mucoprotein (pepsin digested mucoprotein, water-soluble mucoprotein, and water-soluble mucus purified by equilibrium density-gradient centrifugation in cesium chloride) inhibited adhesion between single baby hamster kidney cells (labeled by growing monolayers in the presence of radiosulfur-labeled methionine) and confluent monolayers of baby hamster kidney cells grown in scintillation vials. Comparable concentrations of bovine serum albumin, glycogen, and hyaluronic acid had no effect on adhesion. The inhibition of the adhesion by the gastric mucoprotein was consistent with results of the radioiodine-labeled mucoprotein-binding experiments and showed that the binding was a cell surface phenomenon.

7416 GASTRIN CONCENTRATIONS IN UPPER GASTROINTESTINAL MUCOSA IN DOGS. *(E.)* Watson, L. C.; Reeder, D. D.; Becker, H. D.; LaGrone, L.; Thompson, J. C. (Univ. Texas Med. Br., Galveston). *Surgery* 76(3):419-422, 1974.

Total gastrin content was determined in mucosa from different levels of the gastrointestinal tracts from 9 healthy mongrel dogs (20-25 kg weight). The highest concentration of gastrin was found in the antral mucosa, with concentrations becoming progressively smaller as tissue more distal to the stomach was extracted. Average total gastrin contents for the 9 dogs, tabulated by mucosal level, were as follows: fundus, 4028 ng; antrum, 296,800 ng; proximal duodenum, 1072 ng; distal duodenum 1308 ng; proximal jejunum, 1892 ng; distal jejunum, 2207 ng; and ileum, 1138 ng. Total gastrin content in the entire small bowel mucosa plus the gastric fundic mucosa was only 4% of the total amount of gastrin measured in the gastric antral mucosa, with the major part of fundic and antral mucosal gastrin consisting of the small heptadecapeptide molecular form. While the content of gastrin in extra-antral mucosa of the dog is not nearly as large as in man, future gastric physiology studies should recognize that extra-antral sources of gastrin exist and are of physiologic importance.

7417 EFFECTS OF BURIMAMIDE, AN ANTAGONIST OF H-2 HISTAMINE RECEPTORS, IN THE GASTRIC FISTULA DOG. *(E.)* Hirschowitz, B. I. (Div. Gastroenterol., Univ. Alabama, Birmingham). *Am. J. Dig. Dis.* 19(9):811-817, 1974.

Step-dose responses (45 min) in 6 gastric fistula dogs (average weight 21.8 kg, with Komarov esophagostomy and gastric cannula) were examined for the effect of a 500 μg/kg/hr infusion of burimamide, an H-2 histamine receptor antagonist, acting against histamine (2-100 μg/kg/hr), pentagastrin (0.1-5.0 μg/kg/hr), betazole (50-5000 μg/kg/hr), and 2-deoxy-D-glucose (100 mg/kg). Histamine dose responses in the 6 dogs with and without the burimamide background were essentially alike, with the same volume, acid, chloride, potassium, and pepsin output. Acid and especially pepsin output, as well as volume, chloride and potassium outputs, were reduced by the same dose of burimamide when given as background to betazole. Pentagastrin administration to 3 of the dogs against the burimamide background resulted in a 10% reduction of acid output and a 90% reduction of pepsin output. Burimamide had little effect on the shape of either the acid or pepsin output curves of dogs administered 2-deoxy-D-glucose; if anything, the acid output was increased by burimamide. Larger doses of burimamide, 1-5 mg/kg/hr, produced side effects, especially retching and diarrhea, which precluded studies of these doses. The decrease in pepsin secretion with pentagastrin stimulation, where acid output was only minimally reduced, and the lack of response following stimulation with 2-deoxy-D-glucose, were in contrast to previous findings with another H-2 antagonist, metiamide, where pepsin output with 2-deoxy-D-glucose or urecholine was increased while acid output was decreased.

7418 CO_2 DIFFUSION INTO FROG GASTRIC MUCOSA AS RATE-LIMITING FACTOR IN ACID SECRETION.

(E.) Kidder, III, G. W.; Montgomery, C. W. (Univ. Maryland Sch. Dent., Baltimore). *Am. J. Physiol.* 227(2):300-304, 1974.

Steady-state acid secretory rates in gastric mucosa from the bullfrog (*Rana castebeiana*) were measured with a Radiometer Titrigraph, using 0.10 N sodium hydroxide in mucosal fluid as the titrant, to verify whether such mucosa can be made to secrete at apparently normal rates in the absence of exogenous carbon dioxide by replacing the bicarbonate in the serosal medium with phosphate, acetate, or succinate at pH 4.5. Removal of all CO_2 and bicarbonate reduced the secretory rate to 24 ± 3% of the control value obtained with standard solutions of 5% CO_2 on both the mucosal and serosal sides of the tissue. Replacement of carbonate by phosphate at pH 4.4, in the absence of CO_2, raised the rate to control values of 98 ± 5%. Replacement of carbonate with 25 mM of acetate, succinate, lactate, or citrate raised acid secretory rates to 116 ± 5%, 116 ± 4%, 59 ± 4%, and 34 ± 4% of control values. Increasing the standard 5% CO_2 solutions to 10% CO_2 on both serosal and mucosal surfaces gave maximum secretion, while inhibition was observed at 20% CO_2 concentrations, perhaps resulting from oxygen limitation. Calculations of the diffusional system involved in CO_2 entry indicated that the rate-limiting step is likely to be the diffusion of CO_2 into the tissue. The use of 10% CO_2 concentrations on both serosal and mucosal sides of the gastric tissue is recommended for further studies since this change results in a 10-20% increase in acid secretory rate as compared to 5% CO_2 on both sides and nearly doubles the rate as compared to 5% CO_2 on the serosal side alone.

7419 ORIGIN OF GASTRIN IN GASTRIC JUICE. *(E.)*

Jordan, Jr., P. H.; Yip, B. S. S. C. (Baylor Coll. Med., Houston, Tex.). *Am. J. Surg.* 128(3):336-339, 1974.

Four dogs were prepared with a Heidenhain pouch, an innervated antral pouch separated from the fundus by a mucosal bridge, and a gastric fistula of the vagally innervated portion of the stomach. Gastrointestinal continuity was reestablished by gastrojejunostomy. Gastric secretion was stimulated by constant perfusion of the antrum with a suspension of liver powder or by s.c. betazole injection. Both methods of stimulation produced an increase in gastric secretion from both the gastric fistulas and the Heidenhain pouches. As the acid secretion increased, the concentration and total amount of gastrin in the gastric juice also increased. There was a direct correlation between the amounts of acid and gastrin in the gastric juice from both the gastric fistulas and the Heidenhain pouches. With liver perfusion, the serum gastrin levels increased, peaking 1 hr after perfusion was begun; with betazole stimulation, there was no significant change in serum gastrin. The data indicate that gastrin in the gastric juice originates in the antrum or some extragastric source and is cleared from the blood by the fundic mucosa. Its rate of appearance in the gastric juice is directly related to the secretory activity of the parietal cells.

7420 EFFECT OF HISTAMINE, PENTAGASTRIN AND THEOPHYLLINE ON THE PRODUCTION OF CYCLIC AMP IN ISOLATED GASTRIC TISSUE OF THE GUINEA PIG.

(E.) Karppanen, H. O.; Neuvoneu, P. J.; Bieck, P. R.; Westermann, E. (Med. Coll., Hanover, Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 284(1):15-23, 1974.

The effects of histamine, pentagastrin, and theophylline on the production of cyclic adenosine monophosphate were studied in minced gastric tissue and isolated gastric mucosa of the guinea pig. Theophylline (10^{-3} M), but not histamine (10^{-3} M), increased cyclic AMP by 180 pM/g in the presence of high concentrations of minced tissue (200-300 mg/2 ml incubation medium); whereas histamine (6 x 10^{-4} M), but not theophylline (10^{-3} M) caused a slight elevation of cyclic AMP in small amounts of isolated gastric mucosa (2-4 mg protein/2 ml). Histamine and theophylline in combination caused marked elevations in cyclic AMP levels in both minced tissue and isolated mucosa. The increase of cyclic AMP was inversely related to the amount of minced tissue in the incubate and was inhibited in isolated mucosa by the histamine H_2-receptor antagonist burimamide. The histamine H_1-receptor blocking agent diphenhydramine had no such inhibiting effect. Pentagastrin, either alone or in combination with theophylline, did not significantly change the cyclic AMP level in isolated mucosa. The results support the view that the histamine-induced secretion of gastric acid is mediated *via* cyclic AMP formed in response to stimulation of histamine H_2-receptors. Pentagastrin-induced stimulation of gastric acid, on the other hand, does not appear to be mediated by cyclic AMP in parietal cells.

7421 COMPARATIVE STUDY OF PYLORIC AND FUNDIC ACID PROTEASES IN THE GUINEA PIG GASTRIC MUCOSA: EVIDENCE FOR A PYLORIC PEPSINOGEN. *(E.)*

Cheret, A. M.; Soumarmon, A.; Lewin, M.; Amar-Costesec, A.; Bonfils, S. (Hosp. Bichat, Paris, France). *Comp. Biochem. Physiol.* [*A*] 49A(2):241-249, 1974.

Enzymatic studies were performed on homogenates of pyloric and fundic mucosa obrained from 12 groups of guinea pigs (each group consisting of 3-15 animals) to determine the enzymatic criteria and electrophoretic patterns of acid proteases from pyloric extracts with reference to pepsinogen from the fundic part of the stomach. Very similar results were obtained for both tissues. The Michaelis constant was defined at approximately 10^{-4} M. Proteolytic activity, studied for pH ranging from 1.0-6.5 at an ionic strength of 0.125 M, had an optimum at pH 1.6 and a temperature of 50 C. The activation energy was 10 kcal/M of substrate. Heat inactivation curves did not differ for pyloric and fundic extracts, and electrophoretic patterns were similar for both extracts. The close similarity of the enzymatic behavior and electrophoretic pattern for both the pyloric and fundic extracts support the evidence for pyloric pepsinogen strongly identical to fundic pepsinogen in the guinea pig.

7422 AN ATPase FROM DOG GASTRIC MUCOSA: CHANGES OF OUTER pH IN SUSPENSIONS OF MEMBRANE VESICLES ACCOMPANYING ATP HYDROLYSIS. *(E.)* Lee, J.; Simpson, G.; Scholes, P. (Biochem. Dept., ICI Pharm. Div., Macclesfield, Cheshire, England). *Biochem. Biophys. Res. Commun.* 60(2):825-832, 1974.

An ATPase system with similar properties to a potassium-stimulated magnesium-dependent ATPase isolated in the microsomes of bullfrog oxyntic cells is demonstrated for microsomal fractions isolated from dog gastric mucosa. Michaelis constant data for ATP of Mg-ATPase are reviewed for microsomal and mitochondrial fractions of gastric mucosa from the dog, cat and frog (*R. temporaria*). Gramicidin, valinomycin, and nigericin enhance the Mg-ATPase activity of the microsomal fraction from dog gastric mucosa when assayed in the presence of K ions, establishing a similarity between this mammalian system and the amphibian systems studied previously. Similar observations can also be made with microsomal fractions from cat gastric mucosa. Microsomal Mg-ATPase from the gastric mucosa of the dog, cat, and frog has a Km for ATP in the region of 20-25 μM and can be differentiated from the mitochondrial Mg-ATPase by the value of this coefficient. The Mg-ATPase isolated from the dog gastric mucosa studied appears to be located in the ion impermeable membrane of microsomal vesicles, and ATP hydrolysis driven changes of the outer pH in suspensions of microsomal vesicles can be observed. The data are consistent with the ATP hydrolysis driven entry of hydrogen ions across the vesicle membrane.

7423 AMOUNTS OF ACID AND OF CHLORIDE IN THE RESIDUAL GASTRIC CONTENTS IN HEALTHY PERSONS. *(E.)* Williams, R. H. M.; Hunt, J. N. (Guy's Hosp. Med. Sch., London, England). *Guys Hosp. Rep.* 122(1/2):161-167, 1973.

A method is described for determining the amount of acid and chloride in the resting stomach of humans. Subjects, (4 women and 8 men) who fasted overnight, had instilled and immediately recovered 250 ml of distilled water *via* a nasogastric tube. Acid concentration of the recovered fluid was determined by electrometric titration while chloride content was assessed by titration with silver nitrate in the presence of nitric acid using a silver electrode. Actual total gastric acid and chloride was then calculated from these data. Under these conditions, the mean H^+ content of the stomach was 0.9 mM with 75% of the 118 estimations being less than 1 mM. Mean gastric chloride content was 3.1 mM. The mean volume of gastric secretion was 22 ml with a mean acidity of 38 mM/liter. Based on these findings, the amount of gastric acid is small compared to the relative antacid content of most commercial antacid preparations.

Pancreas

7454 PROTEIN OUTPUT BY THE IN VITRO RABBIT PANCREAS. *(E.)*

Welch, R. W.; Littman, A. (VA Hosp., Hines, Ill.). *J. Appl. Physiol.* 37(2): 235-238, 1974.

The protein output of the pancreas in response to pancreozymin and acetylcholine was measured with a modification of the *in vitro* rabbit pancreas preparation described by Rothman. Direct bath administration of either pancreozymin (15 clinical U) or acetylcholine (0.40 mg/kg bath) caused prompt increases in protein output in all experiments. However, administration of a second dose, 20-80 min later, failed to cause increased production of protein. *In vitro* preparations were then modified so that the arterial supply was preserved and used as the stimulus route. In 3 experiments, hourly doses of pancreozymin (15 clinical U) caused the pancreas to respond repetitively. In 4 experiments, 4 different doses of acetylcholine (2, 4, 8, and 16 μg) given in randomized order at hourly intervals invariably produced repetitive responses. In 3 of the experiments, the responses were clearly proportional to the log of the dose, suggesting *in vitro* secretory activity. A single experiment with 3 different doses of pancreozymin also demonstrated a log-linear relation. The *in vitro* rabbit pancreas responds in a more physiologic fashion when secretory stimulants are given by artery.

7455 MODULATION, BY FOOD, OF HORMONAL SYSTEM REGULATING RAT PANCREATIC SECRETION. *(E.)*

Felber, J. P.; Zermatten, A.; Dick, J. (Cantonal Hosp., Univ. Lausanne, Switzerland). *Lancet* (7874): 185-187, 1974.

A study was made of the effect of different food substrates on the mucosal production of factors acting on the endocrine and exocrine functions of the pancreas. Loads of 2 g/kg glucose, arginine, lysine, peanut oil, or protein hydrolysate were given p.o. through a stomach tube to donor rats. The duodenum was removed at various times after food was given and extracts of duodenal mucosa were injected into an *in situ* pancreas preparation in receptor rats. The effect of the extract was determined by measuring immunoreactive insulin levels in the portal vein and amylase and trypsin activities in the pancreatic juice of receptor rats. Glucose and arginine, but not lysine, increased the β-cytotropic activity of the mucosal extracts. In contrast, extracts taken 45 to 60 min after peanut oil inhibited insulin release. Duodenal extracts taken 30 min after glucose ingestion stimulated amylase but not trypsin activity in pancreatic juice, whereas extracts taken 5 and 45 min after ingestion of a protein hydrolysate stimulated trypsin but not amylase activity. These findings suggest the possibility of a hormonal system which is modulated by different food substrates and influences both endocrine and exocrine pancreas functions.

7456 A COMPARISON OF ENZYME ACTIVITIES IN DUODENAL ASPIRATE FOLLOWING INJECTION OF SECRETIN, CAERULEIN, AND CHOLECYSTOKININ. *(E.)*

Vandermeers-Piret, M. C.; Vandermeers, A.; Rathe, J.; Christophe, J.; van der Hoeden, R.; Wettendorff, P.; Delcourt, A. (Univ. Brussels Med. Sch., Belgium). *Digestion* 10(3):191-204, 1974.

Pancreatic α-amylase, protease, trypsin, chymotrypsin and lipase activities were studied in pancreatic secretions obtained by duodenal aspiration in 32 healthy subjects at various times following stimulation by i.v. injection of secretin (1 U/kg), cerulein (40 ng/kg), or cholecystokinin (1 Ivy dog U/kg) alone or in combination. In 18 subjects secretin was injected followed 60 min later by cerulein. A maximum rise in hydrolase concentrations was noted within 10 min after cerulein administration for the 2 proteases and lipase, and within the first 5 min for amylase. Secretin followed by cholecystokinin was given to 6 subjects with a response similar to that observed in the secretin-cerulein group. A 3rd group of 8 subjects received combined secretin-cerulein followed by cholecystokinin. Although a rapid elevation in hydrolase activity was noted after the secretin-cerulein injection, subsequent cholecystokinin stimulation provoked a further 3-fold increase in trypsin and chymotrypsin concentrations within 10 min with lesser elevations of amylase and lipase. In general, lipase and amylase response was delayed with respect to that of the 2 proteases, and it is suggested that trypsin or chymotrypsin levels may be more indicative of pancreatic activity than is lipase.

7457 PANCREATIC ACINAR CELLS: USE OF A Ca^{++} IONOPHORE TO SEPARATE AND RELEASE FROM THE EARLIER STEPS IN STIMULUS-SECRETION COUPLING. *(E.)*

Williams, J. A.; Lee, M. (Dept. Physiol., Univ. California, San Francisco). *Biochem. Biophys. Res. Commun.* 60(2):542-548, 1974.

The divalent calcium ionophore A23187 was used to stimulate artificially the secretion of amylase from pancreatic acinar cells obtained from fasted male white Swiss mice. The pancreatic fragments were incubated in Krebs-Henseleit bicarbonate solution, and amylase released into the medium was assayed with amylose azure blue as the substrate. Pancreatic calcium uptake was determined by incubating the pancreas in a medium containing $^{45}Ca^{++}$, followed by postincubation for 1 hr in a Hepes buffered Ringer containing 10 mM lathanum chloride for subsequent scintillation counting. The Ca ionophore had no effect on the release of amylase from mouse pancreas fragments in the absence of calcium, but reintroduction of Ca to the medium rapidly increased amylase release in a manner similar to that observed with cholinergic stimulants. Uptake of radioactive calcium by pancreatic fragments was increased by A23187. Tetracaine and dinitrophenol at concentrations which block cholinergic stimulated enzyme release blocked ionophore induced release, whereas atropine did not. None of the inhibitors studied affected the ionophore-induced calcium uptake. The findings emphasize the importance of Ca in the control of amylase secretion and demonstrate the possibility of studying the release process independent of the steps by which normal stimulants increase intracellular Ca.

SECRETION AND METABOLISM

Hepatobiliary Tract

7463 BILE PRODUCTION IN FASTED AND FED PRIMATES. *(E.)* Strasberg, S. M.; Siminovitch, K. A.; Ilson, P. G. (Dept. Surg., Univ. Toronto, Canada). *Ann. Surg.* 180(3):356-363, 1974.

Bile flow was studied in fasted and fed rhesus monkeys to determine whether availability of food or species differences influenced previous experimental data suggesting that monkeys and dogs differ in bile salt independent flow rate and in ability of bile salt secretion to influence bile flow. In the fasting experiments, sodium cholate (2-6 mM/24 hr), sodium taurocholate (2-8 mM/24 hr), and monkey bile (50-200 ml/24 hr) were infused into the duodenum. In the feeding experiments, only sodium cholate was infused. Bile flow was linearly related to bile salt secretion rate in both fasted and fed primates. Bile salt independent flow was extremely variable in fasted primates during infusion of conjugated and unconjugated bile salts, or bile. Bile salts collected from the 5 experimental monkeys were almost 100% conjugated with the exception of 1 animal who was apparently deconjugating infused bile salts due to bacterial contamination. Frequent small feedings resulted in an increased and stabilized bile salt independent flow. These studies indicate that the differences found in previous experiments are probably due to variations in experimental design. The present results may be useful in planning studies of bile formation, especially in biliary tract obstruction.

7464 ENHANCING EFFECT OF CALCIUM IONS ON TRANSPORT OF CHOLESTEROL FROM AQUEOUS SODIUM TAUROCHOLATE-LECITHIN MICELLAR PHASE TO OIL PHASE. *(E.)* Surpuriya, V.; Higuchi, W. I. (Coll. Pharm., Univ. Michigan, Ann Arbor). *J. Pharm. Sci.* 63(8): 1325-1326, 1974.

The influence of calcium ions on the transport of cholesterol from bile-salt lecithin micelles into an oil phase was studied. The experiments involved the preparation of master emulsions with hexadecane and their dilution in sodium taurocholate solutions containing calcium chloride and/or sodium chloride. Radioactive cholesterol was added to the oil for release experiments or the sodium taurocholate-lecithin solutions for uptake experiments. As the calcium ion concentration increased, the sterol transport rate increased until a limiting rate was reached with about a 0.03 M concentration of calcium ions. This limiting rate corresponded to an interfacial barrier permeability coefficient of about 1 x 10^{-6} cm/sec, which was 35-40 times larger than that obtained in the absence of calcium. These results are consistent with the interfacial barrier-controlled mechanism in which the bile salt-lecithin micelle is involved in the rate-determining step at the aqueous-lipid interface. Sodium alone had little effect on the interfacial barrier permeability coefficient. When sodium and calcium ions were both added to the sodium-taurocholate system, the interfacial barrier permeability coefficient for cholesterol increased to 2 x 10^{-6} cm/sec, indicating a synergistic rather than additive effect. Calcium ions may have a more specific effect than sodium ions and could play a key role in lowering the free energy of the activated complex involved in the transport process.

7465 THE SENSITIVITY OF FUNCTION TESTS IN DETECTING LIVER DAMAGE IN THE RAT. *(E.)* Cutler, M. G. (Univ. Birmingham Med. Sch., England). *Toxicol. Appl. Pharmacol.* 28(3):349-357, 1974.

Wistar strain male rats were treated with carbon tetrachloride vapor (160 mg/liter 5 min/day) or sodium selenate (24 mg/liter in drinking water) for 5 months to determine the sensitivity of liver function tests. The hippuric acid test, plasma albumin concentration, and the BSP test were the most sensitive in revealing long-term impairment of liver function. Each of these tests, as well as plasma glutamic pyruvic transaminase activity, showed significant differences between rats of the treated and control groups. Changes in the structure of the liver were more evident than changes in the function. Centrilobular necrosis, fibrosis, and fatty infiltration were apparent in the rats given carbon tetrachloride. Periportal fibrosis, small areas of necrosis, and post necrotic scarring of the liver were seen in the rats given selenate. Both groups of rats showed no significant weight gain. In the carbon tetrachloride-treated animals there was a progressive decrease in weight gain as fibrosis became more severe. Histopathologic examination and plasma pyruvic transaminase were sensitive parameters in detecting liver damage and degree of liver cell necrosis, resp. None of the function tests paralleled the degree of liver fibrosis at 5 months, although some tests showed a correlation with the degree of necrosis. Both liver function tests and histopathological examinations are required for a satisfactory assessment of hepatic integrity in rats exposed to toxic materials.

7466 ATTEMPT TO PRESERVE THE ISCHEMIC LIVER WITH HYDROGEN PEROXIDE: EXPERIMENTAL STUDY ON 21 DOGS.

(Fr.) Depadt, G.; Laurent, J. C.; Bournoville, M.; Verhaeghe, M.; Lagache, G. (Fac. Med. Pharm., Univ. Lille, France). *Lille Chir.* 28(1/2):39-50, 1973.

In experiments performed on 21 male and female dogs, a catheter was inserted into the splenic or ileal vein as far as bifurcation of the portal vein so that the hepatic parenchyma could be perfused. A mesenteric-caval anastomosis was then made to decompress the splanchnic system. The hepatic and gastroduodenal arteries were successively clamped off, and the vein containing the catheter was ligated near the portal bifurcation so that the liver could be perfused while portal blood flow was suppressed. In 21 dogs (group 1), portal perfusion of 100-200 ml hydrogen peroxide (1.5% solution in physiological saline) was begun 30-45 min before blood vessels were clamped off. Then hydrogen peroxide was replaced with 200-300 ml Ringer's solution at 4 C. Hydrogen peroxide was perfused both before and after induction of ischemia in 11 dogs (group 2). The concentration of hydrogen peroxide was the same as in group (1) with the exception of 3 cases in which a 4% solution was used and 2 cases in which an 8% solution was used. Four of these 21 operated dogs served as controls and were not perfused with hydrogen peroxide. Of the 17 experimental animals, 12 died and 5 survived. The death rate increased with the duration of ischemia: 1 of 4 dogs died when the duration of ischemia was 70 min, 1 of 2 after 80 min, 7 of 8 after 90 min, and 3 of 3 after 100 min. While 4 of 10 dogs in group (1) survived, only 2 of 11 survived in group (2). The higher survival rate in group (1) is attributed to the moderate hypothermia obtained when hydrogen peroxide was replaced with Ringer's solution at 4 C. Examination of dogs that died after 48 hr showed blockage of subhepatic veins was the cause of death in 3 cases and hemoperitoneum in 1. Prenecrotic or necrotic lesions found at autopsy consisted of centrilobular necrosis, marked diffuse congestion, structural disorganization, and diffuse liver cell degeneration with atrophy and acidophilia. Determinations of ATP, lactate, and the lactate/pyruvate ratio in the liver, performed before, during, and after ischemia, showed no difference between experimental animals and controls, even when the concentration of hydrogen peroxide was increased to 8%. These findings indicate that portal perfusion of hydrogen peroxide is not effective in alleviating the effects of hepatic ischemia.

7467 THE SUBCELLULAR DISTRIBUTION OF COPPER, ZINC AND IRON IN LIVER AND KIDNEY. CHANGES DURING COPPER DEFICIENCY IN THE RAT.

(E.) Alfaro, B.; Heaton, F. W. (Dept. Biol. Sci., Univ. Lancaster, England). *Br. J. Nutr.* 32(2):435-445, 1974.

The subcellular distribution of copper, zinc, and iron was investigated in liver and kidney homogenates from 2 groups of 24 weanling male Wistar albino rats randomly selected and fed Cu-deficient or control diets for up to 126 days. Most of the Cu and Zn in control animals was observed in the supernatant fraction, while the highest proportion of Fe was found in the microsomal fraction. Copper deficiency reduced the concentration of the metal in all fractions; but the depletion of copper was most severe and developed most rapidly in the supernatant fraction, indicating that the soluble cytoplasm is the site of Cu storage in the cell. The Fe content of the liver increased during Cu deficiency, with Fe being deposited preferentially in the mitochondria. All of the Cu and most of the Zn in the liver and kidney supernatant fractions occurred in 4 protein-containing fractions that were of similar molecular weights in both organs. A fraction of molecular weight 30,000 was primarily concerned with Cu storage in mature rats. The reduction of liver Zn during Cu deficiency appeared to be the result of impaired intestinal absorption. A small amount of Cu is apparently necessary to facilitate Zn absorption.

7468 EFFECT OF ALTERATIONS OF THE SPECIFIC ACTIVITY OF THE INTRACELLULAR ACETYL COA POOL ON APPARENT RATES OF HEPATIC CHOLESTEROGENESIS.

(E.) Dietschy, J. M.; Brown, M. S. (Univ. Tex. Southwestern Med. Sch., Dallas). *J. Lipid Res.* 15 (5):508-516, 1974.

The specific activity of the intramitochondrial acetyl coenzyme A (CoA) was determined in liver slices of female Sprague-Dawley-derived rats subjected to various manipulations known to alter the rate of cholesterogenesis (fasting, cholesterol feeding, biliary or lymphatic diversion, biliary obstruction). Initial experiments to determine the magnitude and variability of endogenous dilution of the intramitochondrial acetyl CoA pool when radiocarbon-labeled acetate was used as the precursor for cholesterol synthesis resulted in 27-49% of the theoretical specific activity expected if no endogenous dilution occurred. These values could not be used to correct the flux of labeled carbon from radiocarbon-labeled acetate into cholesterol since the cytosolic acetyl CoA pool that gives rise to cholesterol is not in equilibrium with the intramitochondrial pool. In subsequent experiments, radiocarbon-labeled octanoate, which is rapidly oxidized intramitochondrially to acetyl CoA which feeds both the intra- and extramitochondrial metabolic pathways, was used to determine true flux rate of C_2 units into cholesterol and other products. With this substrate, the specific activity of the intracellular acetyl CoA pool was 54-71% of the expected specific activity. After correction for endogenous dilution, the C_2 flux into cholesterol varied from 335-459 nM/g/hr in control animals, was suppressed 10- to 40-fold in animals subjected to fasting and cholesterol feeding, and increased into the range of 1500 nM/g/hr after derepression with cholestyramine feeding or biliary diversion. Good agreement between the corrected C_2 flux rate from octanoate into cholesterol and microsomal hydroxymethylglutaryl CoA reductase activity in the same liver was obtained for conditions in which the synthetic rates were varied over a 100-fold range.

7469 IMPORTANCE OF TESTES IN INDUCTION OF HYPERPLASTIC NODULES, CARCINOMAS, AND CIRRHOSIS OF LIVER IN A X C MALE RATS INGESTING 0.025% N-2-FLUORENYLDIACETAMIDE. *(E.)* Reuber, M. D. (Natl. Cancer Inst., Bethesda, Md.). *J. Natl. Cancer Inst.* 53(3):883-886, 1974.

The dependence of hepatic carcinogenesis on the testes was studied in 4 groups (23-26 animals each) of inbred A X C male rats ingesting 0.025% N-2-fluorenyldiacetamide (F-diAA). The experimental groups consisted of intact rats with normal testes, rats with one normal testis, rats with one atrophic testis related to a congenital defect, and rats without testes. The incidence of carcinomas and the number of rats with multiple carcinomas, and metastases were highest in intact rats. The incidence and size of the carcinomas not only decreased in animals with one or both testes removed but also decreased in relation to the bulk and weight of the testis in rats from the other groups. Carcinoma incidence was lowest in rats with both testes removed. The results confirmed the importance of the testes in F-diAA hepatic carcinogenesis, making this model valuable for studies on hepatic carcinogenesis.

7470 AN ORGAN CULTURE OF RAT LIVER. *(E.)* Mattheyse, F. J.; Balinsky, J. B. (Dept. Chem., Univ. Witwatersrand, Johannesburg, South Africa). *S. Afr. J. Sci.* 70(3):90, 1974.

An organ culture of rat liver is described which consists of 1 mm-thick slices of liver supported by filter paper. The paper rests on the edges of the center well of a Conway unit which contains culture medium. The medium consists of 50% bovine serum, 10% whole egg ultra-filtrate, and 40% M199 in Hank's balanced salt solution; and the culture is maintained in an atmosphere of 95% oxygen and 5% carbon dioxide at 20 C for periods of up to 24 hr. Sections of adult liver cultures stained after 24 hr with hemotoxylin-eosin showed about 80% viability; some necrosis was seen in the tissue interior at distances more than 0.3 mm from the surface, with the degree of necrosis being a function of the culture slice thickness. Tissue viewed in the electron microscope showed all organelles intact, though there appeared to be some dilation of cytoplasmic and mitochondrial membranes. Pulse-labeling the cultures with tritiated orotate and leucine after 0, 12, and 24 hr resulted in the appearance of label in trichloroacetic acid-precipitable fractions of homogenates, indicating active protein and RNA synthesis. No decrease in the incorporation rate occurred after 24 hr. Specific activities of urea cycle enzymes in the culture remained virtually unchanged during the 24-hr incubation period. Glutamate dehydrogenase, which is inducible by cyclic-AMP *in vivo*, was also induced *in vitro* in this culture and showed a 2-fold increase in specific activity compared to that in normally cultured controls after 24 hr in the presence of 0.4 mm dibutyryl cyclic AMP. Neonatal and early postnatal liver cultured in this way for 24 hr appeared normal when viewed with either light or electron microscopy and incorporated label into both RNA and protein.

7471 THE ISOLATION OF HORMONE-SENSITIVE RAT HEPATOCYTES BY A MODIFIED ENZYMATIC TECHNIQUE. *(E.)* Zahlten, R. N.; Stratman, F. W. (Inst. Enzyme Res., Univ. Wisconsin, Madison). *Arch. Biochem. Biophys.* 163(2):600-608, 1974.

A modified enzymatic technique for the isolation of rat hepatocytes that exhibit a glucagon response similar to the perfused liver is described which does not require a temperature-controlled perfusion chamber. Major modifications include: a temperature-controlled apparatus for the recirculating perfusion of the isolated liver, the use of substrate-fortified calcium-free Krebs-Henseleit bicarbonate buffer, and high perfusion rates which lead to the isolation of hepatocytes with normal ultrastructure and metabolic activities. The flow rate of the recirculating system should be above 60 ml/min for sufficient oxygenation and rapid digestion. The calcium-free perfusate buffer is prepared from the following solutions: 80 ml 0.154 M sodium chloride, 4 ml 0.154 M potassium chloride, 3 ml water, 1 ml 0.154 M potassium hydrogen phosphate, 1 ml 0.154 M magnesium sulfate (hydrated), 21 ml 1.3% sodium bicarbonate, 4 ml 0.16 M sodium pyruvate, 7 ml 0.1 M sodium fumarate, 4 ml 0.16 M sodium L-glutamate, and 5 ml 0.3 M glucose. The calcium-free incubation buffer contains: 100 ml 0.154 M NaCl, 4 ml 0.154 M KCl, 3 ml H_2O, 1 ml 0.154 M KH_2PO_4, 1 ml 0.154 M $MgSO_4 \cdot 7H_2O$, 21 ml 1.3% $NaHCO_3$, and 1.5% gelatin. Experiments with male Sprague-Dawley rats indicate that from 400-500 million cells can be routinely isolated from 8-10 g liver, independent of the collagenase preparations applied. Electron microscopy and the trypan blue exclusion method indicate 90-95% cell viability. The use of gelatin in the incubation medium is preferred to albumin Fraction V or fatty acid-free albumin which tend to inhibit gluconeogenic rates from various substrates in calcium-free media. Addition of calcium chloride to the incubation medium strikingly improves gluconeogenesis from lactate. Various procedures are given for calculating the number of cells corresponding to 1 g wet liver tissue.

7472 SYNTHESIS OF ALPHA-FETOPROTEIN BY MEMBRANE-BOUND POLYSOMES OF RAT ASCITES HEPATOMA CELLS. *(E.)* Kanai, K.; Endo, Y.; Oda, T.; Tanaka, N. (1st Dept. Med., Univ. Tokyo, Japan). *Cancer Res.* 34:1813-1815, 1974.

The ability of free and membrane-bound polysomes of rat ascites hepatoma cells (AH-66) to synthesize α-fetoprotein (AFP) was investigated and the intracellular site of AFP synthesis was determined. AH-66 cells were collected by peritoneal puncture 7 days after inoculation of the tumor cells and were transplanted i.p. to male Donryu rats weighing 100-150 g. Both the free and membrane-bound polysomes incorporated ^{14}C-leucine into AFP *in vitro*, though the amount of radioactivity incorporated into the antiserum-precipitable AFP fraction by membrane-bound polysomes was 20-90 times higher than that incorporated by free polysomes. The results indicate that AFP is synthesized mainly on membrane-bound polysomes in rat ascites hepatoma cells, suggesting that AFP in hepatomas belongs to excretory proteins such as serum albumin.

7473 BILE FORMATION IN THE INTACT PIG. *(E.)* Egger, G.; Kutz, K.; Strebel, H.; Bircher, J.; Weber, M.; Scholl, E.; Preisig, R. (Sch. Med., Univ. Berne, Switzerland). *Am. J. Vet. Res.* 35(9): 1203-1208, 1974.

Bile formation was studied in 6 adult nonanesthetized Swiss white pigs (females), previously cholecystectomized and equipped with a Thomas duodenal cannula, during i.v. infusions of sodium taurocholate. Relative steady states of bile flow were achieved by cholinergic blockade. Linear relations were obtained for bile flow and elimination of inorganic electrolytes with bile salt excretions ranging from 18-118 μEq/min; thus, 0.01 ml water, 1.87 μEq sodium, 0.06 μEq potassium, 0.24 μEq bicarbonate, and 0.69 μEq chloride were excreted/μEq of bile salt. It was possible to define a bile salt-independent fraction of bile, averaging 0.15 ml/min. Canalicular bile formation was assessed with radiocarbon-labeled erythritol in 2 short-term studies with pigs given general anesthesia. Erythritol clearance values were identical with the collected bile volume at low bile salt excretion rates, while at high bile salt excretion rates the bile flow exceeded erythritol clearance by approximately 10%. The results indicate that bile salt formation in the pig, as in man, depends mainly on the excretion of bile salts. The erythritol clearance data suggest that the relative large bile salt-independent fraction defined for the pig is of hepatocytic origin.

7474 CHEMICAL MODULATION OF EARLY CARBON TETRACHLORIDE LIVER INJURY. *(E.)* Reynolds, E. S.; Moslen, M. T. (Peter Bent Brigham Hosp., Boston, Mass.). *Toxicol. Appl. Pharmacol.* 29(3):377-388, 1974.

Histochemical analysis of liver sections from young male Charles River rats given 1:1 dilutions of carbon tetrachloride (0.26-26 mM/kg) in mineral oil by stomach tube and i.p. injections of chemical agents which modulate early *in vivo* CCl_4 effects was performed to investigate the toxic interaction of CCl_4 with liver endoplasmic reticulum. Alterations in known parameters of CCl_4 injury were compared between control rats and experimental rats receiving β-diethylaminoethyl-3,3'-diphenylpropyl acetate (SKF 525A, 100 mg/kg), promethazine (50 mg/kg), N,N'-diphenyl-p-phenylenediamine (DPPD, 600 mg/kg), α-tocopherol acetate or ethylenediaminetetraacetic acid (EDTA, 400 mg/kg). Such agents either inhibit the binding of CCl_4 with cytochrome P-450 or have free radical sequestering and/or antioxidant activities. The extent of suppression of glucose-6-phosphatase staining and increase in stainable calcium were examined at 1 hr after poisoning; lipid conjugated diene contents, NADPH-NT reductase, glucose-6-phosphatase, and oxidative N-demethylase activities of microsomes, *in vivo* protein synthesis, and cell sap RNA were determined 2 hr after poisoning with 26 mM CCl_4/kg. All the chemical modulators either wholly or partially prevented loss of *in vivo* protein synthesis 2 hr after CCl_4 administration. α-Tocopherol and DPPD reduced the extent of histochemically demonstrable glucose-6-phosphatase suppression and blocked the appearance of stainable calcium. Pretreatment with SKF 525A reduced oxidative N-demethylase activity of liver endoplasmic reticulum and also moderated the increase in lipid-conjugated diene following CCl_4; however, SKF 525A was without effect on the magnitude of loss of histochemically determined glucose-6-phosphatase or the influx of stainable calcium. The qualitative differences between the effects of SKF 525A and α-tocopherol on CCl_4-induced changes in liver endoplasmic reticulum indicated that the chlorocarbon may interact at 2 or more loci in the membrane.

7475 HEPATOCELLULAR TOLERANCE TO CARBON TETRACHLORIDE INDUCED INJURY IN THE RAT: A STUDY OF ITS NATURE AND POSSIBLE MODE OF EVOLUTION. *(E.)* Das, P. K.; Chopra, P.; Nayak, N. C. (All-India Inst. Med. Sci., New Delhi). *Exp. Mol. Pathol.* 21(2):218-236, 1974.

Histochemical, microscopic, and α-fetoprotein immunologic studies were performed on male Sprague-Dawley rats given carbon tetrachloride (25-500 μl/100 g) p.o. through a stomach tube The severity of hepatic injury, as assessed by mortality and structural and biochemical alterations, was dose-dependent. Prior exposure of animals to a 25 μl dose of CCl_4 afforded almost complete protection against the severe and lethal effects of a 500 μl dose. The state of tolerance was achieved about 24 hr after the protective dose and continued for the next 48 hr. The tolerant hepatocytes appeared large with vacuolated and clumped cytoplasm. Electron microscopic examination revealed proliferation of rough endoplasmic reticulum and close packing of membrane-attached ribosomes, with polysomes similar to those in prenatal liver cells. α-Fetoprotein was detected in some of the tolerant animals, suggesting that the development of tolerance might be due to alteration of the entire cell to a type having a different complement of enzymes, as in the fetal hepatocyte. Fatty change continued to occur in the tolerant animals following reexposure even though more serious pathological changes were absent, indicating that the toxic effects of CCl_4 might possibly have separate pathways of evolution.

7476 SECRETION OF SERUM ALBUMIN BY ENZYMATICALLY ISOLATED RAT LIVER CELLS. *(E.)*

Weigand, K.; Otto, I. (Univ. Wurzburg Med. Sch., Germany). *FEBS Lett.* 46(1):127-129, 1974.

The net synthesis and secretion of rat serum albumin by enzymatically isolated rat liver cells is described. Protein was determined by the biuret method, albumin by the radial immunodiffusion of Mancini *et al*, and protein-radioactivity by the method of Mans and Novelli. Cell counts were made in a Buerker chamber, and the viability of the cells was estimated by 0.2% Trypan Blue staining. Typical secretion curves of rat serum proteins were obtained from specific radioactivity curves of total protein supernatant after addition of radiocarbon-labeled leucine to the cell suspension. Secretion time was about 10 min as compared to a reported *in vivo* secretion time of 14 min for rat liver. The initial cell suspension contained about 20% Trypan Blue stained cells, with the membranes of the stained cells being defective and perhaps permeable for proteins. A number of cells might also have been destroyed during centrifugation procedures in the isolation. These facts might explain an observed linear component of the measured radioactive protein curves in the supernatant. Serum albumin was not detected in the supernatant before 60 min due to the limited sensitivity of the immunological method. Thereafter, the secretion of albumin was linear for 120 min at a rate of 0.63 $\mu g/10^6$ cells/hr, based on a calculation for a total of $2.39 \pm 0.17 \times 10^6$ cells/ml. A secretion rate of 1.29 $\mu g/10^6$ cells/hr was calculated on the assumption that the stained cells did not synthesize albumin. Assuming that 1 g of liver wet weight contained 1.7×10^8 cells, albumin was secreted at a rate of 45-92 μg/g/hr, as compared to 470 μg reported for fasted liver *in vivo*, 470 μg for isolated perfused liver, and 161 μg for liver slices. After the addition of 0.4 mg/ml puromycin, no protein radioactivity or albumin in the supernatant was found. The basic albumin content of the cell was not released after puromycin addition, suggesting that this albumin pool does not participate in the continual pathway of synthesis and secretion.

7477 STUDIES ON THE BIOGENESIS OF SMOOTH ENDOPLASMIC RETICULUM MEMBRANES IN HEPATOCYTES OF PHENOBARBITAL-TREATED RATS. II. THE SITE OF PHOSPHOLIPID SYNTHESIS IN THE INITIAL PHASE OF MEMBRANE PROLIFERATION. *(E.)*

Higgins, J. A. (Yale Sch. Med., New Haven, Conn.). *J. Cell Biol.* 62(3): 635-646, 1974.

Parallel investigations of the specific activity of the acyltransferases of rough and smooth microsomes from the livers of adult male albino rats confirmed previous cytochemical observations that the acyltransferases involved in the first steps of phospholipid synthesis during new membrane formation are associated with the smooth endoplasmic reticulum in phenobarbital-treated rats but mainly with the rough endoplasmic reticulum in untreated rat liver. The specific activity of the acyltransferases of smooth microsomes rose 3-fold 12 hr after phenobarbital injection (11 mg/g i.p.), while the acyltransferases of the rough microsomes rose slightly, peaking at 3-4 hr and subsequently falling. The latter rise was abolished by treatment of the animal with actinomycin D or puromycin, while that of the smooth microsomes was unaffected. Incorporation of radiocarbon-labeled glycerol into smooth microsome phospholipid was elevated 100% by phenobarbital, while that of the rough microsomes was elevated 15%; this could be accounted for by exchange between the microsomal phospholipids. The phospholipid/protein ratio of the smooth microsomes rose 1.5 times 3-4 hr after phenobarbital injection, while that of the rough microsomes fell slightly. The specific activity of NADPH cytochrome c reductase and NADPH diaphorase rose first in the rough and subsequently in the smooth microsomes at a time coinciding with the return of the phospholipid/protein ratio to the control level. The rise in phospholipid/protein ratio was unaffected by actinomycin D or puromycin. The results indicate that the proliferating smooth membranes are the site of phospholipid synthesis and that the phospholipid/protein ratio of these membranes may change independently.

7478 INDUCTION DEFICIENCY OF THE MICROSOMAL UDPGLUCURONOSYLTRANSFERASE BY 3-METHYLCHOLANTHRENE IN GUNN RATS. *(E.)*

Vainio, H.; Hietanen, E. (Dept. Physiol., Univ. Turku, Finland). *Biochim. Biophys. Acta* 362(1):92-99, 1974.

Induction of microsomal uridine diphosphate (UDP) glucuronosyl transferase by 3-methylcholanthrene (20 mg/kg i.p.) was studied in Wistar rats and in heterozygous and homozygous Gunn rats. The rate of synthesis of *p*-nitrophenylglucuronide by liver microsomes from Gunn strain rats was about 50% that of conventional Wistar rats. The difference was greater in the gastrointestinal mucosa, with Gunn rats exhibiting only about 10% of the UDP glucuronosyl transferase activity of Wistar rats. The hydroxylation step in drug biotransformation (*O*-demethylation of *p*-nitroanisole and hydroxylation of 3.4-benzypyrene) was about equal in the liver microsomes of Gunn and Wistar rats. Aryl hydrocarbon hydroxylase activity in the small intestinal mucosa of Gunn rats was even greater than that in normal Wistar rats. Administration of 3-methylcholanthrene to both normal Wistar and Gunn rats enhanced the drug hydroxylation activity similarly in each rat group; UDP glucuronosyl transferase, however, could not be induced at all in the homozygous Gunn rats, and the heterozygous Gunn rats exhibited a lesser response than that found in the Wistar rats. The existing hepatic UDP glucuronosyl transferase activity in homozygous Gunn rats could, however, be increased *in vitro* by membrane perturbants such as trypsin (5- to 6-fold), digitonin (10-fold), or phospholipase A (7- to 10-fold). The results indicated a constitutional defect in the ability of Gunn strain rats to regulate UDP glucuronosyl transferase activity, though the microenvironment of the drug-metabolizing enzymes appeared to be similar to that in the normal Wistar rats.

7479 BILIARY EXCRETION IN VIVO OF BILE ACIDS SYNTHESIZED BY HEPATOMAS.

(E.) Bricker, L. A.; Marracini, J. V.; Rosenblatt, S.; Kozlovskis, P. L.; Morris, H. P. (Univ. Miami Sch. Med., Fla.). *Cancer Res.* 34(10):2508-2510, 1974.

Normal ACF/Mai female rats on low cholesterol diets and both normal and tumor-bearing (Morris hepatoma 3924A) female rats on tritium-labeled high cholesterol diets received acute bile fistulas and were infused i.v. with radiocarbon-labeled acetate during *in vivo* biliary excretion studies of bile acids synthesized by hepatomas. Prior *in vitro* studies indicated that Morris hepatoma 3924A synthesizes bile acids. Bile acids collected from normal rats on low-cholesterol diets contained radioactive carbon, while bile acids from normal rats on high-cholesterol diets with added tritiated cholesterol contained only tritium. The normal liver appeared to avail itself of either simple precursors of bile acids such as acetate or, alternatively, stored dietary cholesterol. Sterologenically active tissues such as the intestine did not seem to contribute to hepatic bile acid synthesis in the 4-hr time period of the experiments. Hepatoma-bearing rats, in contrast, released bile acids containing both radioactive carbon and tritium in their bile shed when fed tritiated high-cholesterol diets. The origins of these doubly labeled products are suggested to be independent of each other, being of necessity, the tumor and liver, resp.

7480 ULTRASTRUCTURAL EVIDENCE FOR FOETAL LIVER INJURY INDUCED BY IN UTERO EXPOSURE TO SMALL DOSES OF METHYLMERCURY.

(E.) Ware, R. A.; Chang, L. W.; Burkholder, P. M. (Dept. Pathol., Univ. Wisconsin Med. Sch., Madison). *Nature (Lond.)* 251(5472):236-237, 1974.

Ultrastructural examinations for fetal liver injury were performed on 24 pregnant female Sprague-Dawley rats divided into 4 groups of 6 each, with 3 of the groups receiving s.c. injections of 0.5, 0.75, and 1.0 mg of methylmercuric chloride on the 9th day of their gestational cycle. Neither neurological symptoms in the mothers nor gross teratological malformations in the offspring of treated mothers were observed following methylmercuric chloride administration. Newborn pups were anesthetized immediately with ether, and their livers were excised surgically and prepared for microscopic examination. Fetuses from methylmercury-exposed mothers presented a consistent pattern of liver injury, the severity and extent of which was dose dependent. Pathologic changes at the light microscopic level were confined primarily to hepatocytes and consisted of vacuolation, an increase in lysosomal profiles, and cellular necrosis in many cases. Electron microscopic examination of fetal hepatocytes revealed, in addition to the above changes, mitochondrial degeneration, occasional accumulations of lipid droplets, and dilatation of endoplasmic reticulum. Extrusion of hepatocyte cytoplasmic material into the sinusoidal spaces was also common. Mitochondrial changes in hepatocytes consisted of an increasing electronlucid floccular matrix, diminution of cristae, and occasional swelling. The results demonstrated a significant causal relation between maternal exposure to nonteratogenic doses of methylmercury during gestation and fetal liver injury.

7481 EFFECT OF POLINOSINIC-POLYCYTIDYLIC ACID IN DOGS EXPERIMENTALLY INFECTED WITH INFECTIOUS CANINE HEPATITIS VIRUS.

(E.) Wooley, R. E.; Brown, J.; Scott, T. A.; Lukert, P. D.; Crowell, W. A. (Ga. Coll. Vet. Med., Univ. Georgia, Athens). *Am. J. Vet. Res.* 35(9):1217-1219, 1974.

The efficacy of the interferon-inducer double-stranded polyinosinic-polycytidylic acid as an antiviral agent against experimentally induced infectious canine hepatitis was studied in 20 specific-pathogen-free Beagle dogs. Inoculation of dogs with poly I:C (0.2 mg/kg p.o.) 24 hr before i.v. administration of 10^3 plaque-forming U of infectious canine hepatitis virus resulted in longer survival times for treated dogs as compared with nontreated dogs. Dogs treated with poly I:C survived an average of 6.1 days, while controls survived an average of 3.8 days. Interferon was not found in serum samples. However, the sparing effect of poly I:C might be due to the presence of minimal, yet undetectable amounts of circulating interferon that was unable to suppress completely the replication of infectious canine hepatitis virus.

7482 INDEPENDENCE OF CHOLESTEROL AND FATTY ACID BIOSYNTHESIS FROM CYCLIC ADENOSINE MONOPHOSPHATE CONCENTRATION IN THE PERFUSED RAT LIVER.

(E.) Raskin, P.; McGarry, D.; Foster, D. (Univ. Texas Southwestern Med. Sch., Dallas). *J. Biol. Chem.* 249(19):6029-6032, 1974.

Liver slices from male Sprague-Dawley rats were incubated in 5 ml of Kreb's bicarbonate buffer, pH 7.4, containing 4.2 mM sodium 1-^{14}C-acetate or 1.0 mM sodium 1-^{14}C-octanoate in the presence or absence of cyclic AMP. At 5 mM, cyclic AMP caused a 36% depression in the incorporation of 1-^{14}C-acetate into cholesterol and an 82% decrease in its conversion into fatty acids. A similar effect of cyclic AMP at this concentration was noted on cholesterol synthesis from 1-^{14}C-octanoate. At 0.5 mM, cyclic AMP had no effect on the pathway of cholesterol or fatty acid synthesis. Cyclic AMP had no significant effect on CO_2 or ketone body production, suggesting that its effects on cholesterol and fatty acid synthesis were not due to general depression of cellular metabolism. In other experiments, rat livers were perfused for 30 min with 600 µM sodium 1-^{14}C-acetate or 150 µM sodium 1-^{14}C-octanoate in the absence or presence of 10^{-6} M glucagon infused at 1 nM/min. Glucagon caused a 50-fold increase in tissue cyclic AMP levels (0.38 to >16 nM/g) but had no effect on the rates of cholesterol or fatty acid synthesis. This was true with either labeled acetate or octanoate as precursor. Dibutyryl cyclic AMP (0.5 mM) did not inhibit cholesterol or fatty acid synthesis in livers perfused with labeled octanoate. Assays of isolated microsomes showed that the rise in cyclic AMP in intact liver after glucagon treatment did not result in diminished 3-hydroxy-3-methylglutaryl coenzyme A activity. Rates of cholesterol and fatty acid biosynthesis in the intact perfused liver are apparently totally independent of induced changes in intracellular cyclic AMP concentrations over a wide physiological range.

7483 SIALYL TRANSFERASE ACTIVITIES OF RAT ASCITES HEPATOMA CELLS AND RAT LIVER. *(E.)*

Saito, M.; Satoh, H.; Ukita, T. (Fac. Pharm. Sci., Univ. Tokyo, Japan). *Biochim. Biophys. Acta* 362(3): 549-557, 1974.

The effect of cytidine 5'-monophospho-*N*-acetylneuraminic acid (CMP-sialic acid, 10-200 μM) on sialyl transferase activities in rat ascites hepatoma cell homogenate and normal rat liver homogenate was measured using desialized porcine submaxillary mucin as an exogenous acceptor. The K_m values were 0.045 and 0.19 mM for the enzyme of normal rat liver and ascites hepatoma cells, resp. The V of normal rat liver enzyme was 5 times greater than that of the hepatoma cell enzyme. These differences in kinetic constants reflect a quantitative as well as qualitative difference in the enzyme. The ascites hepatoma cell homogenate had 20% of the sialyl transferase activity of normal rat liver homogenates when desialized porcine submaxillary mucin was used as the acceptor and 18% when lactose was the acceptor. The exogenous acceptor, desialized porcine submaxillary mucin or lactose, was removed from the reaction solution and the effect of the enzyme concentration on the incorporation of ^{3}H-sialic acid into endogenous acceptor was determined. Ascites hepatoma cells gave much smaller transfer of radioactivity (50%) than the normal rat liver cells. These results suggested that ascites hepatoma cell homogenate contained acceptors, presumably glycoproteins, that could be utilized by the liver enzymes but not by the hepatoma cell enzymes. Thus, ascites hepatoma cells were homogenized in chloroform-methanol to remove glycolipids. The organic solvent-insoluble fraction without sialyl transferase activity was added to the reaction mixture for sialyl transferase assay, and incorporation of radioactivity into the acid-soluble fraction was examined. The ascites hepatoma cell extract was utilized as an acceptor by normal rat liver enzymes but not effectively by the enzymes in the ascites hepatoma cells. Normal rat liver extract prepared by the same method was not utilized by either enzymes. Therefore, the glycoproteins in hepatoma cells lack a considerable part of the terminal sialyl residues which results in the lower sialyl transferase activity in the hepatoma cells.

7484 A STUDY OF DRUG METABOLISM LINKED TO CYTOCHROME P-450 IN ISOLATED RAT-LIVER CELLS.

(E.) Moldeus, P.; Grundin, R.; Vadi, H.; Orrenius, S. (Dept. Forensic Med., Karolinska Inst., Stockholm, Sweden). *Eur. J. Biochem.* 46(2):351-360, 1974.

The intracellular regulation of drug monooxygenation linked to cytochrome P-450 was studied in liver cells isolated from starved and phenobarbital-pretreated (80 mg/kh for 3 days) male Sprague-Dawley rats. Liver cells were found to catalyze the cytochrome P-450 dependent, oxidative metabolism of alprenolol [1-(2-allylphenoxy)-3-isopropylaminopropanol] at a rate similar to that obtained with the isolated microsomal fraction in the presence of a NADPH-generating system. Alprenolol was rapidly taken up into the liver cells and the apparent Michaelis constant was similar to that obtained with liver microsomes. Further, inhibitors of drug metabolism such as diethylaminoethyl-2,2-diphenylvalerate hydrochloride and metyrapone showed similar inhibitory patterns in the cellular and microsomal systems. With liver cells isolated from control rats, NADPH generation from endogenous substrates was sufficient to support optimal alprenolol metabolism, whereas the addition of glucose or lactate stimulated this rate in liver cells isolated from starved, phenobarbital-treated rats. Inhibitors of mitochondrial respiration such as rotenone, antimycin A and KCN and the uncoupler carbonyl cyanide-*p*-trifluoromethoxyphenyl hydrazone inhibited cellular alprenolol metabolism, presumably by lowering the ATP/ADP ratio thereby interfering with NADPH generation *via* the malic enzyme system; this effect was more pronounced in liver cells from starved rats. Furthermore, in analogy with previous findings, the rate of gluconeogenesis from lactate was inhibited during alprenolol metabolism; this effect in turn was most pronounced in liver cells from phenobarbital-treated rats. The findings indicate that under certain conditions, the level of cytoplasmic NADPH may become rate-limiting for drug metabolism linked to cytochrome P-450 and support the previous assumption that in fed rats, generation of cytoplasmic NADPH is mainly *via* the pentose phosphate shunt whereas the malic enzyme system becomes more important for this purpose during starvation.

7485 THE ISOLATION OF AN AZOBILIRUBIN β-D-MONOGLUCOSIDE FROM DOG GALL-BLADDER BILE.

(E.) Gordon, E. R.; Dadoun, M.; Goresky, C. A.; Chan, T. H.; Perlin, A. S. (Queen Mary Veterans' Hosp., Montreal, Canada). *Biochem. J.* 143(1):97-105, 1974.

An ethyl anthranilate azopigment of bilirubin conjugated to β-D-monoglucoside was isolated from dog gallbladder. Glucose was cleaved from the azopigment by treatment with β-glucosidase (0.5 mg) and β-glucuronidase (0.2 mg/ml). Mild alkaline hydrolysis (sodium methoxide) yielded 2 kinds of components, one water soluble and the other organic soluble. Enzymic analysis, thin-layer chromatography, nuclear magnetic resonance, and combined gas-liquid chromatography and mass spectrometry showed that the water-soluble fraction contained only glucose, primarily β-D-glucose. No evidence for the presence of a disaccharide was obtained. The organic-soluble compounds formed during methanolysis were the isomeric dipyrole azopigments of bilirubin, as indicated by thin-layer chromatography and mass spectrometry. The findings confirm the hypothesis of Fevey *et al* that glucose is a product of mild alkaline hydrolysis of this azopigment from dog gallbladder. The results are unequivocal evidence for the presence of a single β-D-glucopyranose conjugated to bilirubin, and suggest that in this fraction there is no conjugation to a biouronic acid.

7486 DISTRIBUTION OF INORGANIC SULFATE BETWEEN PLASMA, LIVER, AND BILE.

(E.) Williams, J. A.; Kemp, J.; Woodbury, D. M. (College Med., Univ. Utah, Salt Lake City). *Life Sci.* 15(4):741-749, 1974.

The distribution of $^{35}SO_4$ between its inorganic form and its metabolites in plasma, liver and bile of rats was studied by use of paper electrophoresis. Male Sprague-Dawley rats underwent nephrectomy by ligation of the renal pedicles and $^{35}SO_4$ was injected i.p. at various times from 15 min to 12 hr prior to sacrifice. The overall liver sulfate space, calculated from total radioactivity in plasma, bile and liver, varied from 50-100%, but when determined for inorganic $^{35}SO_4$ was constant at 34%. This is considerably higher than that expected for passive distribution and suggests SO_4 is actively transported into liver cells. Overall sulfate bile/plasma ratios were always greater than 1 while the ratio for inorganic sulfate was 0.44, a value consistent with the known bile/plasma electrical potential and suggesting the existence of a steady-state. The finding of the ability of $^{35}SO_4$ to be incorporated into plasma proteins is similar to that previously reported.

7487 COMPARISON OF ANTIGENICITY OF HEPATOMA CELLS, NORMAL LIVER CELLS, FOETAL LIVER CELLS AND CHEMICALLY DAMAGED LIVER CELLS IN GUINEA-PIGS IMMUNIZED WITH HEPATOMATA USING THE MACROPHAGE INHIBITION TEST.

(E.) Desai, H. N.; Dale, M. M. (Dept. Pharmacol., Univ. Coll. London, England). *Br. J. Cancer* 30(2):109-117, 1974.

The macrophage migration inhibition test was used to study the immune responses of guinea pigs immunized with s.c. injections of whole cells of both an allogeneic and a syngeneic hepatoma grown as established cell lines in tissue culture. A clear dose-dependent relation between tumor cell concentration and inhibition of peritoneal exudate cells was seen in immunized animals. No significant migration inhibition occurred in control animals. The migration inhibition was specific for the tumor cell line used for immunization. There was no cross reaction between whole isolated normal liver cells and tumor cells, or between fetal liver cells and tumor cells. Cells from carbon tetrachloride-damaged livers produced an equivalent degree of migration inhibition in both immunized and control animals. In sensitized animals, however, the degree of inhibition caused by CCl_4-damaged cells was significantly lower than that caused by tumor cells. The nonspecific inhibition produced by the CCl_4-damaged cells may have been a toxic phenomenon due to autolysis, a mechanical phenomenon due to obstruction of capillary tubes, or a manifestation of the previously reported autoimmune response to mitochondrial antigens.

7488 A NEW TECHNIQUE FOR IN SITU HEPATIC ISOLATION AND PERFUSION IN THE RABBIT.

(E.) Lerner, M. H.; Epstein, W. H. (New York Univ. Med. Ctr., N.Y.). *J. Surg. Res.* 16(6):611-619, 1974.

A method for isolation and *in situ* perfusion of rabbit liver is described which allows for the separation of hepatic and systemic circulation without requiring shunting of inferior vena caval blood around the liver *via* extracorporeal bypass. Caval circulation is shunted intracorporeally through the liver by a double lumen catheter with an occlusive balloon attachment. The catheter is inserted into the inferior vena cava and passed through the liver so that the occlusive balloon attachment is just past the emptying of the hepatic veins. Perforations in the outer lumen at the junction of the renal veins allow for shunting of the blood from the vena cava through the liver and to the right atrium. Inflation of the balloon attachment prevents mixing of caval and hepatic circulation when the system is in operation. Vena caval circulation is shunted through the bypass catheter while hepatic venous effluent surrounds the bypass catheter and is collected through a small catheter situated at the emptying of the hepatic veins. This catheter passes through the inner lumen of the bypass catheter and exits independently. Both inorganic phosphate and high energy phosphate values obtained from perfused rabbit liver were similar to those in control nonperfused rabbits. A further indication of the structural and metabolic integrity of the perfused liver was the low level of glutamate oxalacetate transaminase in hepatic venous effluents. The *in situ* liver perfusion technique may be used in the study of metabolic processes in the intact organ as well as for the investigation of tissue-tissue interactions. The technique may also be useful in the selective administration of chemotherapeutic agents or drugs in the treatment of liver carcinoma and other hepatic disorders.

7489 EFFECT OF MOLYBDENUM AND COPPER ON RESPIRATION AND OXIDATIVE PHOSPHORYLATION IN HEPATIC MITOCHONDRIA FROM ALBINO RATS.

(Rus.) Mkheian, E. E.; Mashinian, A. Kh. (Erevan Med. Inst., USSR). *Zh. Eksp. Klin. Med.* 12(4):29-34, 1972.

Since molybdenum (Mo) occurs in large quantities in the environment in Armenia, oxidative phosphorylation and oxygen uptake were studied in mitochondria obtained from the livers of rats given Mo (20 and 100 mg/kg/day), Cu (13 or 66 mg/kg/day), or a combination of Mo (20 mg/kg/day) and Cu (13 mg/kg/day) p.o. through a tube for 45 days. In the presence of ADP, the rate of oxygen uptake, measured by using succinate as the substrate, was significantly higher than control values, while the effectiveness of phosphorylation (ADP/O) was decreased in mitochondria from rats given Mo. When rats were given Cu alone, the rate of oxygen uptake in the presence of ADP was decreased as were values for ADP/O. Simultaneous administration of Cu and Mo normalized the rate of oxygen uptake and oxidative phosphorylation in rat liver mitochondria.

7490 DIBENAMINE IMPAIRMENT OF RAT HEPATIC MICROSOMAL ENZYMES AND ITS RELATION TO HEPA-

TOTOXICITY INDUCED BY CCl_4 AND DIMETHYLNITROSAMINE. *(E.)* Stripp, B.; Sipes, I. G.; Maling, H. M.; Gillette, J. R. (Natl. Heart Lung Inst., NIH, Bethesda, Md.). *Drug Metabol. Disposition* 2(5):464-468, 1974.

Dibenamine pretreatment has previously been shown to protect rat liver from the toxic effects of carbon tetrachloride. The effect of dibenamine on the rat liver microsomal mixed-function oxidase system was investigated in this study. Pretreatment of rats with dibenamine HCl (25 mg/kg s.c. 48 and 24 hr before death) decreased the activity of cytochrome P-450-dependent enzymes in hepatic microsomes as judged by the *in vitro* N-demethylation of ethylmorphine and dimethylnitrosamine, and covalent binding of $^{14}CCl_4$ and ^{14}C-dimethylnitrosamine. The decrease in enzymatic activity was probably not due solely to a decrease in the amount of cytochrome P-450, since the observed magnitude of decrease of cytochrome P-450 was less than the degree of inhibition of ethylmorphine N-demethylation and covalent binding of CCl_4. Dibenamine pretreatment may protect rats from the hepatotoxicity of CCl_4 or dimethylnitrosamine by reducing the formation of active metabolites by microsomal enzymes.

7491 TRANSHEPATIC METABOLISM AFTER END-TO-SIDE PORTACAVAL SHUNT IN THE YOUNG PIG. *(E.)* Hickman, R.; Crosier, J. H.; Saunders, S. J.; Terplanche, J. (Med. Sch. Observatory, Cape Town, South Africa). *Surgery* 76(4):601-607, 1974.

End-to-side portacaval shunt was created in 8 pigs aged 40-60 days and metabolic changes were studied by transhepatic sampling techniques and lumbar puncture. Animals were maintained for 2 days postoperatively on i.v. fluids and were then returned o a normal diet. The animals survived a mean of 5 days, with no obvious cause of death but failure o gain weight and inanition. Arterial ammonia evels rose despite maintained hepatic clearance. erebrospinal fluid glutamine levels also rose for he first 2 weeks after shunt and there was signiicant correlation with arterial ammonia levels. ean serum levels of cholesterol, alkaline phosphaase, amylase, and albumin fell after the procedure, ut no changes were noted in acid-base status, osolality, plasma potassium, glucose, aminotranserase, or urea.

492 EFFECT OF ELECTRICAL VAGAL STIMULATION ON CANINE HEPATIC BILE FLOW. *(E.)* Kaminski, . L.; Dorighi, J.; Jellinek, M. (St. Louis Univ. ch. Med., Mo.). *Am. J. Physiol.* 227(2):487-493, 974.

e effects of direct electrical stimulation of the agus nerve on the output and composition of canine epatic bile were evaluated in unanesthetized dogs. le salt concentrations were determined by an autoted modification of the dehydrogenase method. gs were prepared with biliary and gastric fistulas, d electrodes were placed around the vagus nerves. 1 group, the vagus nerves were maintained intact, d in another group they were cut proximal to the electrodes. The nerves were stimulated with 15 V (2.5 msec duration, 50 pulses/sec). Stimulation was evaluated when the enterohepatic circulation was interrupted and when it was maintained by continuous i.v. infusion of sodium taurocholate. When the enterohepatic circulation was maintained, stimulation of cut and intact vagus nerves did not alter bile flow while significantly increasing gastric fistula hydrogen ion output. With the enterohepatic circulation interrupted, stimulation of intact nerves did not alter bile flow; however, stimulation of distal cut ends produced an increase in bile flow and bicarbonate and chloride output. This study indicates that vagal nerve stimulation minimally alters hepatic bile flow and only when the enterohepatic circulation is interrupted.

7493 STUDIES ON THIOACETAMIDE-INDUCED LIVER NECROSIS. *(E.)* Castro, J. A.; D'Acosta, N. D.; De Ferreyra, E. C.; De Castro, C. R.; Diaz Gomez, M. I.; De Fenos, O. M. (Lab. Chem. Biotoxicol., CITEFA, Zufriaegui y Varela, Argentina). *Toxicol. Appl. Pharmacol.* 30(1):79-86, 1974.

Previous reports have indicated that metabolism of thioacetamide to its S-oxide, possibly by the hepatic microsomal cytochrome P-450 hydroxylating system, is necessary for its necrogenic and carcinogenic effects. To gain further insight into thioacetamide-induced liver necrosis, the induction of liver necrosis by thioacetamide (200 mg/kg i.p.) was compared to that by carbon tetrachloride in castrated male Sprague-Dawley rats. At concentrations as high as 20 mM, thioacetamide produced no spectral change on interaction with liver microsomal suspensions, nor did it modify *in vitro* NADPH cytochrome P-450 reductase activity. In contrast to carbon tetrachloride, thioacetamide did not increase peroxidation of microsomal lipids. The ability of thioacetamide to induce liver necrosis was age-dependent. Alterations in the centrilobular zones were 1st observed in 20-day-old rats; 30 day-old rats showed an intense centrilobular necrosis 24 hr after thioacetamide administration. In both 30- and 40-day-old rats, liver cells in the periportal zones were enlarged, and the normal architectural pattern was lost. Thioacetamide produced a greater increase of plasma isocitric dehydrogenase in males than in females, but there was no difference between sham-operated and castrated rats. Thioacetamide-induced liver necrosis was not prevented by prior administration of any of several inhibitors of cytochrome P-450 mediated transformation, and it was as intense in phenobarbital-preinduced rats as in controls. Prior treatment with either cystamine (600 mg/kg p.o.) or disulfiram (1 g/kg p.o.) partially prevented thioacetamide-induced liver necrosis. These results suggest that cytochrome P-450 or NADPH cytochrome P-450 reductase does not mediate the biological activation of thioacetamide.

7494 DECREASED TYROSINE TRANSAMINASE ACTIVITY IN IRON DEFICIENT RAT LIVER. *(E.)* Aye Kyaw; Tin Win; U Hla Pe (Biochem. Res. Div., Dept. Med. Res., Rangoon, Burma). *Biochem. Med.* 11(2): 194-197, 1974.

Tyrosine transaminase activity was assayed in liver homogenates from albino rats fed an iron-deficient diet for 85 days, beginning at age 35 days. Specific activity of the enzyme was 0.38 ± 0.08 nM substrate/mg protein/min in iron-deficient liver compared with 0.63 ± 0.06 nM substrate/mg protein/min in control liver. Addition of pyridoxal phosphate to the assay medium restored the specific activity, suggesting a depletion of the coenzyme pyridoxal phosphate in the iron-deficient rat liver. Tyrosine transaminase activity *in vitro* was not stimulated by addition of ferrous or ferric ions at concentrations from 1.2 X 10^{-5} M to 1.2 X 10^{-3} M. After 85 days of diet, hemoglobin, mean corpuscular hemoglobin concentration, and packed cell volume were decreased in iron-deficient rats while the proportion of reticulocytes was increased. Hepatic iron concentration was 23.0 ± 2.12 μg/g, confirming the nutritional iron deficiency and suggesting that the storage form of iron in the liver was utilized by the iron-deficient animals.

7495 EFFECTS OF VARIOUS BARBITURATES ON HEPATIC MICROSOMAL ENZYMES. A COMPARATIVE STUDY.

(E.) Valerino, D. M.; Vesell, E. S.; Aurori, K. C.; Johnson, A. O. (Milton S. Hershey Med. Ctr., Hershey, Pa.). *Drug. Metab. Disposition* 2(5):448-458, 1974.

Six barbiturates were compared to determine the extent to which they stimulated hepatic microsomal enzymes of mature male rats after 1, 3, 7, and 14 days of daily i.p. administration. Phenobarbital, pentobarbital, secobarbital, thiopental, and barbital stimulated ethylmorphine N-demethylase and aniline hydroxylase activities and increased microsomal cytochrome P-450 content. Stimulatory responses approached or exceeded 200% of control values after 3, 7, and 14 days of daily phenobarbital (100 mg/kg) administration. Responses exceeding 200% of control values were elicited by barbital (150 mg/kg) during the 14-day observation period. Considerably less stimulation occurred with pentobarbital, secobarbital, and thiopental, and none with hexobarbital. Compared on a molar basis, phenobarbital was the most potent stimulatory agent for each microsomal parameter after 3 daily i.p. injections. Correlation coefficients between partition coefficients for these six barbiturates and their stimulatory potencies were less than 0.45 and were considered not to be biologically significant. Oral administration of phenobarbital (100 mg/kg), secobarbital (75 mg/kg), or hexobarbital (150 mg/kg) for 3 consecutive days did not significantly alter the stimulatory response of an identical i.p. dose of each barbiturate. An association appears to exist between plasma half-lives of phenobarbital (10.1 hr), pentobarbital (2.3 hr), and hexobarbital (36.2 min), and their stimulatory potencies. Hepatic radioactivity 24 hr after administration of these 3 barbiturates was directly related to their stimulatory potencies.

7496 BILE ACID METABOLISM IN MAMMALS: VII. STUDIES ON SEX DIFFERENCES IN DEOXYCHOLIC ACID METABOLISM IN ISOLATED PERFUSED RAT LIVER.

(E.) Fisher, M. M.; Price, V. M.; Magnusson, R. J.; Yousef, I. M. (Dept. Med., Univ. Toronto, Canada). *Lipids* 9(10):786-794, 1974.

Sex differences involved in the hepatic metabolism of deoxycholic acid were studied in the isolated perfused livers of Wistar rats. In 20 perfusions, 10 with livers of male and 10 with livers of female rats, 30 μM deoxycholic acid was added to the perfusion medium. In 10 additional perfusions, 5 male and 5 female, 1 μM deoxycholic acid was added. In 10 of the high dose studies, and in the 10 low dose studies, 1 μC deoxycholic acid-C-24-C^{14} was added to 100 ml perfusion medium after 2 hr of baseline perfusion, and the studies were continued another 3 hr. Biliary bile acids were analyzed by combined thin layer and gas chromatography, and the radioactivity of the perfusion medium and liver documented. Although there was no sex difference in total bile acid secretion in the high dose studies, there were sex differences in the bile acid secretion rate and in the quantitative secretion of individual bile acids. The biliary secretion of deoxycholic acid and cholic acid was immediate in the female studies and delayed in the male, and the amounts of cholic acid and sulfated deoxycholyltaurine secreted were considerably greater in the male studies. In the low dose studies, the female liver converted more deoxycholic acid to cholyl-taurine than did that of the male rat. There are, therefore, sex differences in the hepatic metabolism of deoxycholic acid, but these differences are not impressive when physiological amounts of deoxycholic acid are presented to the liver.

7497 EFFECTS OF DIETARY CHOLESTEROL UPON BILE ACID METABOLISM IN GUINEA PIG. *(E.)*

Hansma, H.; Ostwald, R. (Dept. Nutr. Sci., Univ. Calif., Berkeley). *Lipids* 9(10):731-737, 1974.

The bile acid metabolism of young, male albino guinea pigs, fed a diet with or without cholesterol, was studied in a search for the factor(s) which prevent adequate control of their body cholesterol pool. The results indicate that in the cholesterol-fed guinea pig, the synthesis (and excretion) of bile acids is at least 3 times greater than in controls. This is the result of a doubling of the fractional turnover rate and a smaller increase of the pool size. The major increase of the bile acid pool was in the liver. The following factors may contribute to this cholesterol accumulation in the guinea pig: continued endogenous synthesis of cholesterol; continued high rate of intestinal absorption; or failure of neutral sterol excretion to increase. The main bile acid in gallbladder bile and small intestine was chenodeoxycholic acid, with smaller amounts of 7-ketolithocholic and ursodeoxycholic acids. In the cecum, large intestine, and feces, the major bile acid was lithocholic acid.

7498 EFFECT OF 4-METHYLPYRAZOLE AND PYRAZOLE ON THE INDUCTION OF FATTY LIVER BY A SINGLE DOSE OF ETHANOL. *(E.)*

Khanna, J. M.; Kalant, H.; Loth, J.; Seymour, F. (Dept. Pharmacol., Univ. Toronto, Canada). *Biochem. Pharmacol.* 23(21):3037-3043, 1974.

The effects of pyrazole and 4-methylpyrazole on triglyceride accumulation was investigated in the livers of male and female Wistar rats. Pyrazole (272 mg/kg), 4-methylpyrazole (200 mg/kg), or saline was injected i.p. into fasted male and female rats. Ten min later, ethanol (4 or 6 g/kg) or an equicaloric dose of sucrose was given by stomach tube. Hepatic triglyceride levels were measured at 6, 12 or 16 hr after the gavage. With the smaller dose of ethanol, pyrazole reduced the accumulation of triglyceride at 6 hr in females, but not at 12 or 16 hr. In males, ethanol induced relatively little triglyceride accumulation at 6 hr and pyrazole did not affect this, but at 16 hr the triglyceride levels in the ethanol-pyrazole group had not risen as much as in the ethanol-saline group. In contrast to pyrazole, 4-methylpyrazole by itself increased liver triglyceride content, and significantly increased the triglyceride accumulation caused by the smaller dose of ethanol in both males and females at 16 hr. However, 4-methylpyrazole caused a significantly smaller triglyceride accumulation in females at 6 hr after the ethanol, but not in males. With the larger dose of ethanol, both pyrazole and 4-methylpyrazole decreased the accumulation of triglyceride at 16 hr in males. It is concluded that ethanol *per se*, ethanol as a metabolic substrate, and pyrazoles as pharmacological agents with complex actions, may all contribute to the development of acute fatty liver. Because of this complexity of actions, the pyrazole derivatives do not appear to be suitable tools for resolving the problems concerning the mechanism of the production of fatty liver.

7499 ACTIVATION OF ETHANOL METABOLISM BY 2,4-DINITROPHENOL IN THE ISOLATED PERFUSED RAT LIVER.

(E.) Seiden, H.; Israel, Y.; Kalant, H. (Dept. Pharmacol., Univ. Toronto, Canada). *Biochem. Pharmacol.* 23(16):2234-2237, 1974.

The effect of 2,4-dinitrophenol on the rate of ethanol metabolism was studied in the isolated perfused rat livers of male Wistar rats in which ethanol is metabolized at a rate which is 60-70% of that found *in vivo*. Perfusion rate was 5-6 ml/min/g of liver wet weight at a constant portal venous pressure of 14 cm of water. Livers were first perfused with 1 liter of Ringer solution and then with the same solution containing 3 mM ethanol. 2,4-Dinitrophenol was infused at a constant rate through the open end of the Fisher portal vein cannula. The basal rate of ethanol metabolism was on the order of 1.5-2.0 μM/g liver/min. 2,4-Dinitrophenol in concentrations up to 60 μM increased both the rate of oxygen consumption and the rate of ethanol metabolism. Higher concentrations of 2,4-dinitrophenol further increased the rate of oxygen consumption but had no effect on that of ethanol metabolism or even reduced it. After rather long perfusions in the presence of 2,4-dinitrophenol (more than 5 min), removal of the uncoupler did not reverse the rate of alcohol metabolism to basal values, as it did to the rate of oxygen consumption. The data indicate that the rate of ethanol metabolism is limited by the mitochondrial oxidative capacity.

7500 INTERACTION OF ETHANOL AND DRUGS IN 'ACATALATIC' HEPATIC MICROSOMES.

(E.) Vatsis, K. P.; Schulman, M. P. (Univ. Illinois Coll. Med., Chicago). *Clin. Res.* 22(4):671A, 1974.

The proposed similarity of a hepatic microsomal ethanol-oxidizing system to the drug-metabolizing pathway was investigated with mutant acatalasemic mice (C_sb) with thermolabile tissue catalases which become rapidly inactivated at 37 C and pH 7.4. NADPH- and H_2O_2-linked ethanol oxidation was absent in hepatic microsomes from untreated or phenobarbital-treated C_sb mice. Microsomal catalase from C_sb mice was totally inactivated after 15 min at 37 C, while that from genetic controls (C_sa) was unaffected after 1 hr at 37 C. Catalase addition restored ethanol oxidation by microsomes from untreated or phenobarbital-treated C_sb to corresponding values obtained with C_sa mice. NADPH-oxidase and alcohol dehydrogenase activities were equal in both strains and did not exhibit thermolability. Microsomes from both strains showed equal rates of drug metabolism and NADPH-cytochrome c reductase activities, and responded with comparable stimulation to phenobarbital. Despite the absence of ethanol metabolism in C_sb microsomes, ethanol inhibited drug metabolism to the same extent in microsomes from both strains. It was concluded that: 1) catalase + NADPH oxidase are responsible for a microsomal ethanol-oxidizing system; 2) the drug-metabolizing pathway is not a common detoxifying route for ethanol and drugs; and 3) inhibition of the drug-metabolizing pathway by ethanol is nonspecific and unrelated to ethanol oxidation.

7501 PRIMARY SYNTHESIS OF MONOHYDROXY BILE ACIDS IN THE LIVER.

(Ger.) Back, P.; Schumacher, H.; Gerok, W. (Med. Clin., Univ. Freiburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1300-1303, 1972.

By using gas chromatography and mass spectrometry, bile acids were identified and quantitatively determined in 24-hr urine specimens obtained from an infant with extrahepatic biliary atresia at ages 5-11 months and in material from a liver biopsy taken at age 5 months. In addition to 3β-hydroxy-5-cholen-24-oic acid, which has recently been identified in urine from children with liver disease, the following compounds were identified in the urine specimen obtained at age 5 months: cholesterol and cholic, 3α-, 6α-, 7α-trihydroxycholanoic, deoxycholic, chenodeoxycholic, 3α-, 6α-dihydroxycholanoic, lithocholic, and ursodeoxycholic acids. In later urine specimens, primary synthesis of lithocholic acid decreased, while synthesis of 3α-, 7β-dihydroxycholanoic acid increased. Since intestinal bacteria played no role in the transformation of chenodeoxycholic acid into 3α-, 7β-dihydroxycholanoic acid in this case, this acid must be synthesized by a 7β-hydroxylation reaction. Incubation of the mitochondrial fraction of liver homogenate with $4\text{-}^{14}C$-cholesterol gave lithocholic, ursodeoxycholic, deoxycholic, cholic, and chenodeoxycholic acids, traces of unidentified dihydroxy acids, and a compound tentatively identified as cholestenoic acid. When 3β-hydroxy-5-cholen-24-oic acid was incubated with liver cell fractions, lithocholic and *allo*-lithocholic acids were synthesized. The microsomal fraction and cytosol produced primarily *allo*-lithocholic acid, while the mitochondrial fraction and cytosol synthesized more lithocholic acid. These results demonstrate that in its early stages of development or in severe liver disease, the human liver is capable of directly synthesizing monohydroxy bile acids by mitochondrial side-chain oxidation.

7502 HEPATOTOXICITY OF BROMOTRICHLOROMETHANE—BOND DISSOCIATION ENERGY AND LIPOPEROXIDATION. *(E.)* Koch, R. R.; Glende, Jr., E. A.; Recknagel, R. O. (Sch. Med. Case Western Reserve Univ., Cleveland, Ohio). *Biochem. Pharmacol.* 23(20):2907-2915, 1974.

The pro-oxidant actions of bromotrichloromethane ($BrCCl_3$), CCl_4, and $CHCl_3$ were studied in a supplemented microsome-supernatant system derived from rat liver. $BrCCl_3$ was 200 times more active than CCl_4 in promoting peroxidative decomposition of rat liver microsomal lipids. $CHCl_3$, with a higher bond dissociation energy (i.e., a lesser tendency for homolytic bond cleavage) elicited virtually no pro-oxidant response *in vitro*. At equivalent doses (1 ml/kg p.o. through stomach tube), $BrCCl_3$ produced 3 times as much lipoperoxidation in male Sprague-Dawley rats as did CCl_4. Rapid appearance of conjugated diene absorption in rats treated with a lethal dose of $BrCCl_3$ (1 ml/kg) suggested a positive correlation between massive lipoperoxidation of the hepatic endoplasmic reticulum and early death of the rat. Administration of a small dose of $BrCCl_3$ (0.025 ml/kg) caused a dramatic fall in liver microsomal cytochrome P-450. Rats with low levels of cytochrome P-450 due to pretreatment with $BrCCl_3$ were completely resistant to a lethal dose of CCl_4 (5 mg/kg). All rats given 1 ml/kg $BrCCl_3$ died within 2-6 hr. Such rapid death supports the suggestion that $BrCCl_3$ may have extrahepatic sites of action.

7503 AN EXAMINATION OF THE METABOLISM OF THIAMIN BY RAT LIVER ALCOHOL DEHYDROGENASE. *(E.)* Dalvi, R. R.; Sauberlich, H. E.; Neal, R. A. (Vanderbilt Univ. Sch. Med., Nashville, Tenn.). *J. Nutr.* 104(11):1476-1483, 1974.

Thiamin and its thiazole moiety, 5-(2-hydroxyethyl)-4-methylthiazole, were examined as substrates for purified rat liver alcohol dehydrogenase (RLADH). Although thiamin itself was a poor substrate for the enzyme, its thiazole moiety was oxidized at a faster rate than ethanol. With incubation times greater than 5 min, the major product of the *in vitro* reaction of the thiazole moiety of thiamin with RLADH was the corresponding acid, 4-methylthiazole-5-acetic acid (thiazole acetic acid). A possible mechanism is proposed for this RLADH-catalyzed 2-step oxidation of the thiazole moiety first to 4-methylthiazole-5-acetaldehyde followed by oxidation of the compound to thiazole acetic acid. *In vivo* administration of the RLADH inhibitor pyrazole (200 mg/kg i.p.) followed 30 min later by ^{35}S-thiamin (500 μg/kg) decreased the amount of thiamin excreted in urine as thiamin acetic acid and thiazole acetic acid. Pyrazole also had a significant effect on the rate of excretion of administered thiazole (100 mg/kg i.p.) as thiazole acetic acid. The data indicate that RLADH is involved in the *in vivo* metabolism of thiamin and its thiazole moiety to their corresponding acids.

7504 ALTERATIONS IN HEPATOCYTES AFTER MANIPULATION OF THE DIET: COPPER, ZINC AND CADMIUM INTERACTIONS. *(E.)* Miller, M. L.; Murthy, L.; Basom, C. R.; Petering, H. G. (Univ. Cincinnati, Coll. Med., Ohio). *Am. J. Anat.* 141(1):23-40, 1974.

Morphometric analyses of liver parenchymal cells were performed by electron microscopy on male albino rats fed a semipurified diet supplemented with copper and zinc. These metals were administered in demineralized drinking water to 4 groups of animals at 2 levels: (1) 0.25 μg Cu/ml, 2.5 μg Zn/ml, and (2) 1.0 μg Cu/ml, 10 μg Zn/ml. Cadmium, also administered in the drinking water daily to rats at 17.2 μg/ml, was given to 1 group of animals on each of the 2 semipurified diets. Two groups of rats were given laboratory chow plus 17.2 μg Cd/ml for 71 days and for 280 days. Volume densities of all organelles, as determined from micrographs, diminished significantly when levels of copper and zinc were lowest. Surface densities of rough and smooth endoplasmic reticulum were significantly decreased. Higher levels of copper and zinc produced morphologic and morphometric parameters which fell just below those obtained for rats fed chow. Glycogen accumulation was highest when the levels of metal were low. Lipid inclusions were more frequent with semipurified diets than with chow. Hepatocytes from rats fed the semipurified diet with low copper and zinc plus cadmium demonstrated a significant increase in smooth endoplasmic reticulum compared with animals fed the semipurified diet alone. The smooth endoplasmic reticulum changed little when cadmium was given to rats receiving adequate copper and zinc. Smooth endoplasmic reticulum increased when diets included chow and cadmium whereas rough endoplasmic reticulum decreased. Cup-shaped and elongated mitochondria with longitudinal cristae appeared in hepatocytes from animals fed chow with cadmium. These were not seen with semipurified diets and cadmium.

7505 DIETARY LIPID ASSIMILATION AFTER ACUTE ETHANOL INGESTION IN THE RAT. *(E.)* Mendenhall, C. L.; Greenberger, P. A.; Greenberger, J. C.; Julian, D. J. (Indiana Univ. Sch. Med., Indianapolis). *Am. J. Physiol.* 227(2):377-362, 1974.

The acute ingestion of ethanol (6 g/kg) preceeded by ingestion of a lipid emulsion containing tripalmitin-^{14}C resulted in the development of a fatty liver within 16 hr in male Holtzman rats maintained for 3 days previously on a fat-free diet. ^{14}C-Labeled liver triglycerides increased 4-fold, suggesting a substantial increase in the accumulation of dietary lipids. When the effect of ethanol on the amount of dietary lipids released into the circulation as chylomicrons was evaluated using thoracic duct cannulation, the tagged lipid recovered in the chyle after ethanol treatment was 2 times greater than the controls. When isolated intestinal mucosal cells were prepared from ethanol-treated animals, a significant increase in tagged lipid uptake was observed using either ^{14}C-palmitate or ^{14}C-monopalmitin. After 1 min incubation with ^{14}C-palmitate, the tagged fatty acids were recovered unesterified in the membrane fraction of the cells. The studies suggest that some, as yet undefined, ethanol-induced alteration in cell membrane is responsible for the observed changes.

7506 RETICULOENDOTHELIAL FUNCTION: DETERMINANT FOR SURVIVAL FOLLOWING HEPATIC ISCHEMIA IN THE BABOON. *(E.)* Olcay, I.; Holper, K.; Kitahama, A.; Miller, R. H.; Drapanas, T.; Trejo, R. A.; Di Luzio, N. R. (Tulane Univ. Sch. Med., New Orleans, La.). *Surgery* 74(4):643-653, 1974.

The influence of hepatic ischemia on reticuloendothelial function and on the development of systemic endotoxemia was evaluated and related to subsequent mortality patterns of *Papio papio* baboons. Hepatic ischemia was induced by total normothermic hepatic vascular occlusion. In 1 group of animals this was done without portacaval decompression. In the 2nd group, portacaval shunting was accomplished by interposition of a graft to accomplish an end-to-side anastomosis between the portal vein and inferior vena cava. Of 5 baboons undergoing 60 min of complete hepatic vascular occlusion without venous decompression, 60% manifested endotoxemia in both portal venous and femoral arterial plasma. All 3 animals undergoing 90 min of hepatic ischemia without venous decompression developed systemic endotoxemia. Of 4 animals undergoing 90 min of ischemia with venous decompression, 2 developed endotoxemia. Blood samples obtained from sham-operated and experimental animals prior to occlusion were endotoxin negative. The degree and persistence of endotoxemia did not appear to correlate with the ultimate fate of the animal. In contrast, reticuloendothelial dysfunction, as reflected by the impairment in the clearance of the ^{131}I-triolein reticuloendothelial test-lipid emulsion correlated with ultimate mortality patterns. Baboons which developed phagocytic depression 24 hr after hepatic insult ultimately died, while those which manifested minor modifications of reticuloendothelial function survived. These studies reveal that reticuloendothelial dysfunction may be contributory to fatal outcome in shock due to hepatic ischemia.

7507 THE TREATMENT OF CHRONIC LIVER DISEASE WITH D-PENICILLAMINE. *(E.)* Wildhirt, E. (Acad. Hosp., Kassel, Germany). *Postgrad. Med. J. (Suppl.)* 50(2):42-43, 1974.

The effects of penicillamine treatment (300 mg/day increasing to 1800 mg/day after 4 weeks) were studied in 78 patients with chronic liver disease who had not responded to a 3-month trial of corticosteroids or immunosuppressants. Biochemical parameters measured during treatment were serum bilirubin, total protein, immunoglobulins, aminotransferases, SGOT, SGPT, γ-glutamyl transpeptidase, and BSP. Biopsies were obtained at 6- to 12-month intervals. Four patients died of causes other than liver disease and 26 did not respond to treatment. In 30 patients all biochemical parameters normalized completely; in another 14 there was a marked reduction in transaminase activity, BSP, and immunoglobulin and γ-globulin levels. Histologic follow-up of 39 patients showed that 17 cases of chronic aggressive hepatitis or cirrhosis became inactive with disappearance of periportal cellular infiltrates and of Kupffer cell proliferation. The effect on inflammatory changes was good in another 20 patients. Side effects which necessitated discontinuation of treatment in 12 patients were rashes (4 cases), proteinuria (5), severe nausea (1), thrombocytopenia (1), and agranulocytosis (1). Ten other patients had further inflammatory exacerbations with an increase in transaminases. In contrast to azathioprine, there were no deaths in hepatic coma as a result of acute necrotic exacerbations. Unlike prednisone, which has a similar total incidence of side effects, penicillamine did not cause bleeding from a gastric ulcer, thromboembolism, or sepsis. However, a controlled trial of penicillamine treatment in chronic liver disease is needed. For the present the drug should be used only when other approaches have failed.

7522 PROTEIN BIOSYNTHESIS IN THE LIVER OF X-IRRADIATED MICE. *(E.)* Mukerjee, H.; Goldfeder, A. (Dept. Health, Hosp., New York Univ., N.Y.). *Int. J. Radiat. Biol.* 25(5):445-454, 1974.

7523 EVIDENCE FOR A PROTEOLYTIC SYSTEM IN RAT LIVER MITOCHONDRIA. *(E.)* Lovaas, E. (Sch. Med., Univ. Bergen, Norway). *FEBS Lett.* 45(1):244-247, 1974.

7524 DAILY RHYTHMS IN TYROSINE TRANSAMINASE AND OTHER HEPATIC ENZYMES THAT METABOLIZE AMINO ACIDS: MECHANISMS AND POSSIBLE CONSEQUENCES. *(E.)* Wurtman, R. J. (Dept. Nutr. Food Sci., Mass. Inst. Technol., Cambridge). *Life Sci.* 15(5):827-847, 1974.

7525 LOCALIZATION OF PHOSPHOPROTEINS IN RIBOSOMAL SUBUNITS AND IN FREE AND BOUND POLYSOMES OF RAT LIVER. *(E.)* Pierre, M.; Creuzet, C.; Loeb, J. E. (Sci. Res. Inst. Cancer, Villejuif, France). *FEBS Lett.* 45(1):88-91, 1974.

7526 THE RATE OF CLEARANCE OF XENON FROM RAT LIVER SECTIONS IN VITRO AND ITS SIGNIFICANCE IN RELATION TO INTRACELLULAR DIFFUSION RATES. *(E.)* Evans, A. L.; Busuttil, A.; Gillespie, F. C.; Unsworth, J. (West. Reg. Hosp. Board, Glasgow, Scotland). *Phys. Med. Biol.* 19(3):303-316, 1974.

7527 A RE-EVALUATION OF ENERGY-INDEPENDENT CALCIUM-ION BINDING BY RAT LIVER MITOCHONDRIA. *(E.)* Reed, K. C.; Bygrave, F. L. (Fac. Sci., Australian Natl. Univ., Canberra). *Biochem. J.* 142(3):555-556, 1974.

7528 ISOLATION OF RAT LIVER CELLS CONTAINING CONCANAVALIN-A RECEPTOR SITES. *(E.)* Rojkind, M.; Portales, M. L.; Eugenia, M. (Dept. Cellular Biol., Ctr. Invest. Adv. Studies I.P.N., Mexico City, Mexico). *FEBS Lett.* 47(1):11-14, 1974.

7529 L-LYSINE UPTAKE BY RAT LIVER MITOCHONDRIA. DEPENDENCE ON L-LYSINE CONCENTRATION, pH, AND INDUCED K+ FLUX. *(E.)* Diwan, J. J.; Aram, J. P. (Biol. Dept., Rensselaer Polytechnic Univ., Troy, New York). *Biophys. J.* 14(10):805-808, 1974.

7530 FORMATION OF L-ASCORBIC ACID IN PERFUSED RAT LIVER. *(E.)* Bock, K. W.; Schwarz, L. R. (Toxicol. Inst., Tubingen, Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 284(3):307-310, 1974.

7531 THE ORIGIN OF AN E.S.R. SIGNAL AT g=2·03 FROM NORMAL RABBIT LIVER AND THE EFFECTS OF NITRITES UPON IT. *(E.)* Foster, M. A.; Hutchison, J. M. S. (Dept. Med. Phys., Univ. Aberdeen, Scotland). *Phys. Med. Biol.* 19(3):289-302, 1974.

7532 PIG LIVER PERFUSION WITH MEMBRANE OXYGENATOR: A STUDY OF LIVER VIABILITY BY MEANS OF THE MITOCHONDRIAL RESPIRATION TEST. *(E.)* De Miguel, E.; Fresneda, V.; Gosalvez, M.; Soberon, R.; Martinez, R.; Garcia-Romero, E.; O'Connor, F.; Castillo-Olivares, J. L. (Puerto de Hierro Clin., Madrid, Spain). *J. Surg. Res.* 17(3):186-191, 1974.

7533 OXYGEN EXTRACTION IN THE PIG LIVER BEFORE AND AFTER DEARTERIALISATION. *(E.)* Resch, F.; Hannesson, T.; Aune, S. (Ullaval Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(27):27, 1974.

7534 EVALUATION OF ISCHEMIC DAMAGE TO RAT LIVER MITOCHONDRIA USING THE KREBS-CYCLE. *(E.)* Daniel, A. M.; Beaudoin, J. G. (Roy. Victoria Hosp., Montreal, Canada). *J. Surg. Res.* 17(3):204-209, 1974.

7535 EFFECT OF TOTAL HEPATECTOMY ON SELECTED CEREBRAL SUBSTRATES AND ENZYMES OF THE GLYCOLYTIC PATHWAY AND KREBS CYCLE. *(E.)* Zieve, L.; Nicoloff, D. M. (Minneapolis Veterans Hosp., Univ. Minn.). *Clin. Res.* 22(4):636A, 1974.

7536 COMPARATIVE UPTAKE OF BROMSULPHTHALEIN BY ISOLATED KUPFFER AND PARENCHYMAL CELLS. *(E.)* Stege, T.; Loose, L. D.; Di Luzio, N. R. (Tulane Univ. Sch. Med., New Orleans, La.). *Physiologist* 17(3):338, 1974.

7537 EFFECT OF ISCHEMIA ON HEPATIC PARENCHYMAL AND RETICULOENDOTHELIAL FUNCTION IN THE BABOON. *(E.)* Holper, K.; Olcay, I.; Kitahama, A.; Miller, R. H.; Brettschneider, L.; Drapanas, T.; Trejo, R. A.; Di Luzio, N. R. (Tulane Univ. Sch. Med., New Orleans, La.). *Surgery* 76(3):423-432, 1974.

7538 EFFECT OF SYNTHETIC ESTROGENS AND ESTROGEN-PROGESTIN COMBINATIONS ON THE HEPATIC MICROSOMAL ENZYME SYSTEM. *(E.)* Freudenthal, R. I.; Amerson, E. (Chem. Life Sci. Div., Res. Triangle Inst., Research Triangle Park, N. C.). *Biochem. Pharmacol.* 23(19):2651-2656, 1974.

7539 HORMONAL REQUIREMENTS FOR ACUTE STIMULATION OF RAT LIVER POLYSOME FORMATION BY AMINO ACID FEEDING. *(E.)* Clemens, M. J.; Pain, V. M. (Natl. Inst. Med. Res., London, England). *Biochim. Biophys. Acta* 361(3):345-357, 1974.

7540 EFFECT OF HEXACHLOROBENZENE ON HEPATIC MICROSOMAL ENZYMES IN THE RAT. *(E.)* Stonard, M. D.; Nenov, P. Z. (Med. Res. Council Lab., Carshalton, England). *Biochem. Pharmacol.* 23(15):2175-2183, 1974.

7541 METABOLISM OF ACETANILIDE WITH HEPATIC MICROSOMES AND RECONSTITUTED CYTOCHROME MONOXYGENASE SYSTEMS. *(E.)* Selander, H. G.; Jerina, D. M.; Daly, J. W. (Natl. Inst. Arthritis Metab. Dig. Dis., NIH, Bethesda, Md.). *Arch. Biochem. Biophys.* 164(1):241-246, 1974.

7542 STUDIES ON A HCO_3-STIMULATED ATPase AND CARBONIC ANHYDRASE SYSTEM IN RAT LIVER LYSOSOMES. *(E.)* Iritani, N.; Wells, W. W. (Dept. Biochem., Michigan State Univ., East Lansing). *Arch. Biochem. Biophys.* 164(1):357-366, 1974.

7543 VITAMIN A AND LYSOSOMAL STABILITY IN RAT LIVER. *(E.)* Sudhakaran, P. R.; Kurup, P. A. (Dept. Biochem., Univ. Kerala, Trivandrum, India). *J. Nutr.* 104(11):1466-1475, 1974.

7544 CHANGES IN LYSOSOMAL HYDROLASE ACTIVITY ASSOCIATED WITH MALNUTRITION IN YOUNG RATS. *(E.)* Roobol, A.; Alleyne, G. A. O. (Dept. Med., Univ. West Indies, Kingston, Jamaica). *Br. J. Nutr.* 32(2):189-197, 1974.

7545 REGULATION OF HEPATIC ACETYL COENZYME A CARBOXYLASE BY PHOSPHORYLATION AND DEPHOSPHORYLATION. *(E.)* Carlson, C. A.; Kim, K. (Dept. Biochem., Purdue Univ., West Lafayette, Indiana). *Arch. Biochem. Biophys.* 164(2):478-489, 1974.

7546 ON THE INDUCTION OF TYROSINE AMINOTRANSFERASE IN RAT LIVER BY α-METHYL-*p*-TYROSINE. *(E.)* Ohisalo, J. J.; Hassinen, I. E.; Pispa, J. P. (Dept. Med. Chem., Univ. Helsinki, Finland). *Biochim. Biophys. Acta* 362(1):48-52, 1974.

7547 EFFECT OF PREGNENOLONE-16α-CARBONITRILE AND NEPHRECTOMY ON THE RAT LIVER. *(E.)* Garg, B. D.; Szabo, S.; Tuchweber, B.; Kovacs, K. (Inst. Med. Exp. Surg., Univ. Montreal, Canada). *Exp. Pathol.* 9(3):175-181, 1974.

7548 THE EFFECT OF PHENOBARBITAL AND SODIUM DEHYDROCHOLATE ON THE BILIARY EXCRETION OF METHYLMERCURY IN THE RAT. *(E.)* Magos, L.; MacGregor, J. T.; Clarkson, T. W. (Med. Res. Council Lab., Carshalton, England). *Toxicol. Appl. Pharmacol.* 30(1):1-6, 1974.

7549 ACTION OF METABOLIC HORMONES ON THE FINE STRUCTURE OF RAT LIVER CELLS. III. EFFECTS OF ADRENALECTOMY AND ADMINISTRATION OF CORTISONE. *(E.)* Cardell, Jr., R. R. (Sch. Med., Univ. Virginia, Charlottesville). *Anat. Rec.* 180(2):309-330, 1974.

7550 THE EFFECT OF FASTING ON THE ACYLATION OF CARNITINE AND GLYCEROPHOSPHATE IN RAT LIVER SUBCELLULAR FRACTIONS. *(E.)* Van Tol, A. (Med. Fac., Erasmus Univ., Rotterdam, Netherlands). *Biochim. Biophys. Acta* 357(1):14-23, 1974.

7551 THE EFFECT OF myo-INOSITOL DEFICIENCY ON LIPID METABOLISM IN RATS. II. THE MECHANISM OF TRIACYLGLYCEROL ACCUMULATION IN THE LIVER OF myo-INOSITOL-DEFICIENT RATS. *(E.)* Hayashi, E.; Maeda, T.; Tomita, T. (Shizuoka Coll. Pharm. Sci., Japan). *Biochim. Biophys. Acta* 360(2):146-155, 1974.

7552 THE IN VIVO INCORPORATION OF MANNOSE, RETINOL AND MEVALONIC ACID INTO PHOSPHOLIPIDS OF HAMSTER LIVER. *(E.)* Barr, R. M.; De Luca, L. M. (Natl. Cancer Inst., NIH, Bethesda, Md.). *Biochem. Biophys. Res. Commun.* 60(1):355-363, 1974.

7553 EFFECT OF DIFFERENT ALBUMIN-BOUND FATTY ACIDS ON FATTY ACID AND CHOLESTEROL BIOSYNTHESIS IN RAT HEPATOCYTES. *(E.)* Nilsson, A.; Sundler, R.; Akesson, B. (Dept. Physiol. Chem., Univ. Lund, Sweden). *FEBS Lett.* 45(1):282-285, 1974.

7554 ALTERATIONS IN CHOLESTEROL AND FATTY ACID BIOSYNTHESIS IN RAT LIVER HOMOGENATES BY ARYLOXY ACIDS. *(E.)* Olson, R. J.; Trumble, T. E.; Gamble, W. (Dept. Biochem. Biophys., Oregon State Univ., Corvallis). *Biochem. J.* 142(2):445-448, 1974.

7555 KETOGENESIS IN ISOLATED RAT LIVER MITOCHONDRIA II. FACTORS AFFECTING THE RATE OF β-OXIDATION. *(E.)* Lopes-Cardozo, M.; Van Den Bergh, S. G. (Lab. Vet. Biochem., State Univ., Utrecht, Netherlands). *Biochem. Biophys. Acta* 357(1):43-52, 1974.

7556 KETOGENESIS IN ISOLATED RAT LIVER MITOCHONDRIA. III. RELATIONSHIP WITH THE RATE OF β-OXIDATION. *(E.)* Lopes-Cardozo, M.; Van Den Bergh, S. G. (Lab. Vet. Biochem., State Univ. Utrecht, Netherlands). *Biochem. Biophys. Acta* 357(1):53-62, 1974.

7557 KETOGENESIS IN ISOLATED RAT-LIVER MITOCHONDRIA. IV. OXALOACETATE DECARBOXYLATION: CONSEQUENCES FOR METABOLIC CALCULATIONS. *(E.)* Lopes-Cardozo, M.; Van Den Bergh, S. G. (Lab. Vet. Biochem., State Univ., Utrecht, Netherlands). *Biochim. Biophys. Acta* 357(2):193-203, 1974.

7558 EFFECTS OF PROSTAGLANDIN E_1 (PGE_1) ON ETHANOL METABOLISM IN THE RAT. *(E.)* Lalyre, Y.; Scruggs, W.; Wilson, D. E. (Abraham Lincoln Sch. Med., Univ. Ill., Chicago). *Clin. Res.* 22(4):671A, 1974.

7559 THE EFFECT OF LYSINE ON GLUCONEOGENESIS FROM LACTATE IN RAT HEPATOCYTES. *(E.)* Cornell, N. W.; Lund, P.; Krebs, H. A. (Radcliffe Infirm., Oxford, England). *Biochem. J.* 142(2):327-337, 1974.

7560 STEROIDGLUCURONYL TRANSFERASES, V. FORMATION AND HYDROLYSIS OF OESTROGEN GLUCURONIDES BY THE LIVER, KIDNEY, AND INTESTINE OF THE PIG. *(E.)* Rao, G. S.; Rao, M. L.; Haueter, G.; Breuer, H. (Inst. CLin. Biochem., Bonn, Germany). *Hoppe Seylers Z. Physiol. Chem.* 355(7):881-890, 1974.

7561 EFFECT OF GLUCAGON ON GENERAL PROTEIN DEGRADATION AND SYNTHESIS IN PERFUSED RAT LIVER. *(E.)* Woodside, K. H.; Ward, W. F.; Mortimore, G. E. (Milton S. Hershey Med. Ctr., Hershey, Pa.). *J. Biol. Chem.* 249(17):5458-5463, 1974

7562 ACTIVATION OF GLYCOGENOLYSIS IN PERFUSED RAT LIVERS BY GLUCAGON AND METABOLIC INHIBITORS. *(E.)* Jakob, A.; Diem, S. (Cantonal Hosp., Zurich, Switzerland). *Biochim. Biophys. Acta* 362(3):469-479, 1974.

7563 HETEROGENEITY AND UNUSUALLY HIGH AFFINITY IN THE INTERACTIONS OF ADENOSINE 3':5'-MONOPHOSPHATE WITH SPECIFIC BINDING PROTEINS FROM LIVER AND HEPATOMA CELLS. *(E.)* Mackenzie, III, C. W.; Stellwagen, R. H. (Univ. Southern Calif. Sch. Med., Los Angeles). *J. Biol. Chem.* 249(18):5763-5771, 1974.

7564 DIFFERENCES BETWEEN LIVER AND HEPATOMA CELLS IN THEIR COMPLEMENTS OF ADENOSINE 3':5'-MONOPHOSPHATE-BINDING PROTEIN KINASES. *(E.)* Mackenzie, III, C. W.; Stellwagen, R. H. (Univ. Southern Calif. Sch. Med., Los Angeles). *J. Biol. Chem.* 249(18): 5755-5762, 1974.

7565 STIMULATION BY 6-N,2'-O-DIBUTYRYLADENOSINE 3':5'-CYCLIC MONOPHOSPHATE AND GLUCOCORTICOIDS OF PHOSPHOENOLPYRUVATE CARBOXYKINASE IN THE ISOLATED PERFUSED RAT LIVER. *(E.)* Huttner, W. B.; Krone, W.; Seitz, H. J.; Tarnowski, W. (Univ. Inst. Physiol. Chem., Hamburg, Germany). *Biochem. J.* 142(3):691-693, 1974.

7566 EFFECT OF GLUCAGON, DIBUTYRYL ADENOSINE 3', 5'-CYCLIC MONOPHOSPHATE AND PHOSPHODIESTERASE INHIBITORS ON RAT LIVER PHOSPHORYLASE ACTIVITY AND ADENOSINE 3',5'-CYCLIC MONOPHOSPHATE LEVELS. *(E.)* Ingebretsen, C.; Clark, J. F.; Allen, D. O.; Ashmore, J. (Indiana Univ. Sch. Med., Indianapolis). *Biochem. Pharmacol.* 23(15):2139-2146, 1974.

7567 THE INCORPORATION OF L-[^{14}C]FUCOSE INTO GLYCOPROTEIN FRACTIONS OF LIVER PLASMA MEMBRANES. *(E.)* Riordan, J. R.; Mitranic, M.; Slavik, M.; Moscarello, M. A. (Hosp. Sick Children, Toronto, Canada). *FEBS Lett.* 47(2):248-251, 1974.

7568 A COMPARATIVE STUDY ON DRUG HYDROXYLATION AND GLUCURONIDATION IN LIVER MICROSOMES OF PHENOBARBITAL AND 3-METHYLCHOLANTHRENE TREATED RATS. *(E.)* Vainio, H.; Hanninen, O. (Dept. Physiol., Univ. Turku, Finland). *Acta Pharmacol. Toxicol. (Kbh.)* 35 (1):65-75, 1974.

7569 GLUCURONIDATION IN RAT LIVER AND SMALL INTESTINAL MUCOSA DURING STARVATION AND PHENOBARBITAL TREATMENT. *(E.)* Marselos, M.; Laitinen, M. (Dept. Physiol., Univ. Kuopio, Finland). *Acta Pharmacol. Toxicol.* [*Suppl.*] *(Kbh.)* 35:57, 1974.

7570 GROWTH CONTROL OF DIFFERENTIATED FETAL RAT HEPATOCYTES IN PRIMARY MONOLAYER CULTURE. V. OCCURRENCE IN DIALYZED FETAL BOVINE SERUM OF MACROMOLECULES HAVING BOTH POSITIVE AND NEGATIVE GROWTH REGULATORY FUNCTIONS. *(E.)* Leffert, H. L. (Salk Inst., San Diego, Calif.). *J. Cell Biol.* 62(3):767-779, 1974.

7571 GROWTH CONTROL OF DIFFERENTIATED FETAL RAT HEPATOCYTES IN PRIMARY MONOLAYER CULTURE. VI. STUDIES WITH CONDITIONED MEDIUM AND ITS FUNCTIONAL INTERACTIONS WITH SERUM FACTORS. *(E.)* Koch, K.; Leffert, H. L. (Salk Inst., San Diego, Calif.). *J. Cell Biol.* 62(3):780-791, 1974.

7572 GROWTH CONTROL OF DIFFERENTIATED FETAL RAT HEPATOCYTES IN PRIMARY MONOLAYER CULTURE. VII. HORMONAL CONTROL OF DNA SYNTHESIS AND ITS POSSIBLE SIGNIFICANCE TO THE PROBLEM OF LIVER REGENERATION. *(E.)* Leffert, H. L. (Salk Inst., San Diego, Calif.). *J. Cell Biol.* 62(3):792-801, 1974.

7573 EFFECT OF PHENOBARBITAL ON GROWTH AND STRUCTURE OF NEWBORN RAT HEPATOCYTES IN EXPLANT CULTURES. *(E.)* Guillouzo, A.; Gueguen, C.; Boisnard, M.; Kerbaol, M.; Lenoir, P. (INSERM U-49, Pontchaillou Hosp., Rennes, France). *Digestion* 10(3):222, 1974.

7574 PROTECTIVE ACTION OF DITHIOCARBAMATES ON EXPERIMENTAL LIVER DAMAGE PRODUCED BY CARBON TETRACHLORIDE. *(E.)* den Tonkelaar, E. M.; van Logten, M. J. (Natl. Inst. Publ. Hlth., Bilthoven, Netherlands). *Toxicol. Appl. Pharmacol.* 30(1):96-106, 1974.

7575 EFFECT OF ISOPROPANOL-INDUCED POTENTIATION OF CARBON TETRACHLORIDE ON RAT HEPATIC ULTRASTRUCTURE. *(E.)* Cote, M. G.; Traiger, G. J.; Plaa, G. L. (Fac. Med., Univ. Montreal, Canada). *Toxicol. Appl. Pharmacol.* 30(1):14-25, 1974.

7576 POTENTIATION OF CARBON TETRACHLORIDE HEPATOTOXICITY BY SODIUM NITRITE PRETREATMENT. *(E.)* Suarez, K. A.; Bhonsle, P. (Chicago Coll. Osteopath., Ill.). *Pharmacologist* 16(2):229, 1974.

7577 PLASMA ENZYME ACTIVITY AND HEPATOCELLULAR CHANGES IN THE BEAGLE DOG AFTER SINGLE OR REPEATED ADMINISTRATION OF CARBON TETRACHLORIDE. *(E.)* Lichfield, M. H.; Gartland, C. J. (Imp. Chem. Ind., Ltd., Cheshire, England). *Toxicol. Appl. Pharmacol.* 30(1):117-128, 1974.

7578 EFFECTS OF CCl_4 LIVER DAMAGE ON BILIARY ABSORPTION AND REEXCRETION OF COMPOUNDS ADMINISTERED TO RATS BY RETROGRADE INTERBILIARY INJECTION. *(E.)* Peterson, R. E.; Fujimoto, J. M. (Med. Coll. Wisconsin, Milwaukee). *Toxicol. Appl. Pharmacol.* 29(1):148-149, 1974.

7579 EXPERIMENTAL MODIFICATION OF THE MITOGENIC EFFECT OF METHYL STERCULATE ON RAT LIVER. *(E.)* Scarpelli, D. G. (Univ. Kansas Med. Ctr., Kansas City). *Virchows Arch.* [*Zellpathol.*] 16(2): 211-220, 1974.

7580 STUDIES ON IRREVERSIBLE BINDING OF RADIOACTIVITY FROM [^{14}C]HALOTHANE TO RAT HEPATIC MICROSOMAL LIPIDS AND PROTEIN. *(E.)* Van Dyke, R. A.; Gandolfi, A. J. (Mayo Clin. Mayo Fdn., Rochester, Minn.). *Drug Metab. Disposition* 2(5): 469-476, 1974.

7581 COVALENT BINDING OF SULFUR TO MICROSOMES AND LOSS OF CYTOCHROME P-450 DURING THE OXIDATIVE DESULFURATION OF SEVERAL CHEMICALS. *(E.)* De Matteis, F. (Med. Res. Council Toxicol. Unit, Carshalton, England). *Molec. Pharmacol.* 10(5):849-854, 1974.

7582 EFFECT OF CYCLOHEXIMIDE ON THE DISTRIBUTION OF α-NAPHTHYLISOTHIOCYANATE IN RATS. *(E.)* Lock, S.; Witschi, H.; Skelton, F. S.; Hanasono, G.; Plaa, G. L. (Fac. Med., Univ. Montreal, Canada). *Exp. Molec. Pathol.* 21(2):237-245, 1974.

7583 BIOCHEMICAL EFFECTS OF 3,5-DIETHOXYCARBONYL-1,4-DIHYDROCOLLIDINE IN MOUSE LIVER. *(E.)* Gayathri, A. K.; Padmanaban, G. (Dept. Biochem., Indian Inst. Sci., Bangalore). *Biochem. Pharmacol.* 23(19):2713-2725, 1974.

7584 EFFECT OF 4-METHYLPYRAZOLE AND DIETARY PYRIDOXINE ON ETHANOL-INDUCED ALTERATION OF HEPATIC VITAMIN B_6 METABOLISM. *(E.)* Veitch, R. L.; Lumeng, L.; Li, T. K. (Dept. Med., Indiana Univ., Indianapolis). *Clin. Res.* 22(4):636A, 1974.

7585 ANTAGONISTIC EFFECTS OF DINITROPHENOL AND CYANIDE ON HEPATIC THYROXINE DEIODINATION. *(E.)* Hillier, A. P. (Physiol. Lab., Cambridge, England). *Acta Endocrinol.* 77(1):122-127, 1974.

7586 COMPARATIVE METABOLIC CONVERSION OF AFLATOXIN B_1 TO M_1 AND Q_1 BY MONKEY, RAT AND CHICKEN LIVER. *(E.)* Masri, M. S.; Booth, A. N. (Western Reg. Res. Lab., USDA, Berkeley, Calif.). *Life Sci.* 15(2):203-212, 1974.

7587 EFFECT OF BIPHENYL ON DRUG METABOLIZING ENZYMES OF RAT LIVER. *(E.)* Arvela, P.; Vorne, M. (Dept. Pharmacol., Univ. Oulu, Finland). *Acta Pharmacol. Toxicol.* [*Suppl.*] *(Kbh.)* 35:19, 1974.

7588 EFFECTS OF A POLYCHLORINATED BIPHENYL MIXTURE (AROCLOR 1254) AND DDT ON BILIARY THYROXINE EXCRETION IN RATS. *(E.)* Bastomsky, C. H. (Roy. Victoria Hosp., Montreal, Canada). *Endocrinology* 95(4):1150-1155, 1974.

7589 ANALYSIS OF THE INFLUENCE OF SELECTED NEUROTROPIC AGENTS ON HEPATIC METABOLISM IN RELATION TO ENDOTOXICOSIS. *(E.)* Agarwal, M. K. (Pasteur Inst., Paris, France). *Biochem. Pharmacol.* 23(18):2577-2584, 1974.

7590 HYDROPEROXIDE CATALYZED LIVER MICROSOMAL AROMATIC HYDROXYLATION REACTIONS INVOLVING CYTOCHROME P-450. *(E.)* Rahimtula, A. D.; O'Brien, P. J. (Dept. Biochem., Memorial Univ. Newfoundland, St. John's, Canada). *Biochem. Biophys. Res. Commun.* 60(1):440-447, 1974.

7591 THE RESOLUTION AND RECONSTITUTION OF THE LIVER MICROSOMAL HYDROXYLATION SYSTEM. *(E.)* Lu, A. Y. H.; Levin, W. (Hoffmann-La Roche Inc., Nutley, N.J.). *Biochim. Biophys. Acta* 344(2):205-240, 1974.

7592 RECONSTITUTED LIVER MICROSOMAL ENZYME SYSTEM THAT HYDROXYLATES DRUGS, OTHER FOREIGN COMPOUNDS AND ENDOGENOUS SUBSTRATES. VII. STIMULATION OF BENZPHETAMINE N-DEMETHYLATION BY LIPID AND DETERGENT. *(E.)* Lu, A. Y. H.; Levin, W.; Kuntzman, R. (Hoffmann-La Roche Inc., Nutley, N.J.). *Biochem. Biophys. Res. Commun.* 60(1):266-272, 1974.

7593 EFFECT OF LINALOOL ON HEPATIC DRUG-METABOLIZING ENZYMES IN THE RAT. *(E.)* Parke, D. V.; Rahman, K. M. Q.; Walker, R. (Dept. Biochem., Univ. Surrey, Guildford, England). *Biochem. Soc. Trans.* 2(4):615-618, 1974.

7594 DECREASE AND INHIBITION OF LIVER GLYCOGEN PHOSPHORYLASE AFTER FRUCTOSE. AN EXPERIMENTAL MODEL FOR THE STUDY OF HEREDITARY FRUCTOSE INTOLERANCE. *(E.)* Thurston, J. H.; Jones, E. M.; Hauhart, R. E. (Washington Univ. Sch. Med., St. Louis, Missouri). *Diabetes* 23(7):597-604, 1974.

7595 THE GALLBLADDER OF THE GUINEA PIG: ITS CONCENTRATING AND CONTRACTILE ABILITIES. *(E.)* Shaw, H. M.; Heath, T. J. (Sch. Physiol. Pharmacol., Univ. New South Wales, Kensington, Australia). *Comp. Biochem. Physiol.* [*A*] 49(2): 231-240, 1974.

7596 THE EFFECT OF THE BICARBONATE ION ON THE GALLBLADDER SALT PUMP. *(E.)* Martin, D. W. (Dept. Zool., Univ. Arkansas, Fayetteville). *J. Membr. Biol.* 18(3/4):219-230, 1974.

7597 CARBAMYL PHOSPHATE AND GLUTAMINE STIMULATION OF THE GALLBLADDER SALT PUMP. *(E.)* Martin, D. W.; Murphy, B. (Dept. Zool., Univ. Arkansas, Fayetteville). *J. Membr. Biol.* 18(3/4):231-242, 1974.

7598 DEPENDENCE OF CANINE GALLBLADDER FILLING ON THE INTRINSIC COMPETENCE OF THE INTRAMURAL COMMON BILE DUCT. *(E.)* Tansy, M. F.; Innes, D. L.; Martin, J. S.; Kendall, F. M. (Temple Univ. Sch. Dent., Philadelphia, Pa.). *Physiologist* 17(3):342, 1974.

7599 INTERACTION OF OCTAPEPTIDE-CHOLECYSTOKININ, SECRETIN, AND GASTRIN ON CAT GALLBLADDER IN VITRO. *(E.)* Chowdhury, J. R.; Fara, J. W.; Berkowitz, J. M. (Nassau County Med. Ctr., East Meadow, N.Y.). *Physiologist* 17(3):195, 1974.

7600 ANOTHER LOOK AT REJECTION IN PIG LIVER HOMOGRAFTS. *(E.)* Battersby, C.; Egerton, W. S.; Galderson, G.; Kerr, J. F.; Burnett, W. (Dept. Surg., Univ. Queensland, Brisbane, Australia). *Surgery* 76(4):617-623, 1974.

7601 INDUCTION OF ARYL HYDROCARBON (BENZO[a]-PYRENE) HYDROXYLASE AND TYROSINE AMINOTRANSFERASE IN HEPATOMA CELLS IN CULTURE. *(E.)* Whitlock, Jr., J. P.; Miller, H.; Gelboin, H. V. (Natl. Cancer Inst., NIH, Bethesda, Md.). *J. Cell Biol.* 63(1):136-145, 1974.

7602 EXPRESSION OF PURIFIED MITOCHONDRIAL POLY-(A)POLYMERASE OF HEPATOMAS BY AN ENDOGENOUS PRIMER FROM LIVER. *(E.)* Jacob, S. T.; Rose, K. M.; Morris, H. P. (Milton S. Hershey Med. Ctr., Hershey, Pa.). *Biochim. Biophys. Acta* 361(3):312-320, 1974.

7603 METABOLISM OF EXOGENEOUS CORTISOL IN TUMOR-BEARING RATS. *(E.)* Marc, V.; Donelli, M. G.; Bartosek, I.; Guaitani, A.; Standen, S.; Morselli, P. L. (Mario Negri Inst. Pharmacol. Res., Milan, Italy). *Eur. J. Cancer* 10(7):437-443, 1974.

7604 PREVENTION OF D-GALACTOSAMINE-INDUCED HEPATOCELLULAR AUTOPHAGOCYTOSIS BY CYCLOHEXIMIDE. *(E.)* Rumpelt, H. J.; Albring, M.; Thoenes, W. (Inst. Cytobiol. Cytopathol., Univ. Marburg/Lahn, Germany). *Virchows Arch.* [*Zellpathol.*] 16(2):195-203, 1974.

7605 PROTHROMBIN AND PROCONVERTIN DECOMPOSITION IN RATS WITH EXPERIMENTAL EXTRAHEPATIC CHOLESTASIS. *(Rus.)* Kiianov, V. I. (I. P. Pavlov 1st Leningrad Med. Inst., USSR). *Biull. Eksp. Biol. Med.* 78(7):31-32, 1974.

SECRETION AND METABOLISM

Intestine

7619 GASTRIN IN THE ONTOGENIC DEVELOPMENT OF THE SMALL INTESTINE. *(E.)* Lichtenberger, L.; Johnson, L. R. (V.A. Wadsworth Hosp. Ctr., Los Angeles, Calif.). *Am. J. Physiol.* 227(2):390-395, 1974.

Littermate King-Holtzman inbred cream-colored rats were used to determine the possible relation between observed antral gastrin increases during the beginning of weaning (3rd week of life) and major developmental changes in rat small intestinal development. Two litters of rats were used in 1 experiment, each litter being divided into 2 groups at 14 days of age; 1 group was prevented from weaning, while the 2nd group was allowed to wean. Rats were sacrificed 10 days later. The ratios of gut wet weight/body weight, RNA/body weight, and protein/body weight were significantly lower in nonweaned than weaned rats. Antral gastrin concentration was also significantly lower in nonweaned rats. In a following study, 250 μg/kg of pentagastrin or saline (for controls) was injected s.c. into 14-day-old rats which were prevented from weaning. Ten days of pentagastrin treatment significantly increased the gut weight/body weight, RNA/body weight, and protein/body weight ratios, and these increases were comparable to those seen after weaning. The findings demonstrate that pentagastrin has a trophic effect on intestinal structure of suckling rats and suggest that gastrin may be a mediator between the onset of weaning and the initiation of certain aspects of intestinal development. This role for gastrin is consistent with its well-established action as a gastrointestinal trophic agent and with the fact that the timing of its development coincides with weaning and major intestinal developmental changes.

7620 GASTRIC INHIBITORY POLYPEPTIDE (GIP) STIMULATION BY ORAL GLUCOSE IN MAN. *(E.)* Cataland, S.; Crockett, S. E.; Brown, J. C.; Mazzaferri, E. L. (Div. Endocrinol. Metab., Ohio State Univ., Columbus). *J. Clin. Endocrinol. Metab.* 39(2):223-228, 1974.

Serum levels of gastric inhibitory polypeptide (GIP), glucose, and immunoreactive insulin were measured in 25 normal subjects (19 men and 6 women, mean age 26.1 yr) receiving either p.o. (75 g) or i.v. (25 g) administrations of glucose. Mean serum glucose, immunoreactive insulin, and GIP levels of 21 subjects receiving glucose p.o. (peak at 30 min) were 132 mg/100 ml, 85 μU/ml, and 747 pg/ml, resp., as compared to mean fasting values of 73, 11, and 319, resp. Serum glucose and immunoreactive insulin tended to fall in parallel and returned to fasting levels by 180 min, while the serum GIP remained at peak up to 60 min and was still slightly above fasting level at 180 min. In 4 subjects receiving glucose i.v., glucose and insulin levels were 212 mg/100 ml and 32 μU/ml, resp., and peaked within 10 min, gradually returning to fasting levels by 50 min. However, fasting serum GIP (213 pg/ml) tended to fall by 10 min, was undetectable at 20, 30, and 40 min, and was 191 pg/ml at 50 min. Measurements of portal venous GIP, insulin, and glucose levels in response to p.o. glucose showed a prompt rise in GIP at 2 min when no increase in portal insulin was detectable. Portal GIP remained elevated until 180 min, whereas insulin increased by 5 min and remained slightly above fasting at 180 min. Unlike i.v. glucose which did not stimulate GIP release, p.o. glucose appears to be a potent stimulus for the enteric release of GIP. The mechanism of glucose-stimulated GIP release remains a subject for study.

7621 THE INFLUENCE OF SEROTONIN ON CRYPT CELL PROLIFERATION IN THE JEJUNUM OF RAT. *(E.)*

Tutton, P. J. M. (Dept. Anat., Monash Univ., Clayton, Victoria, Australia). *Virchows Arch.* [*Zellpathol.*] 16(1):79-87, 1974.

The influence of exogenous serotonin and of serotonin-depleting agents on jejunal crypt cell proliferation was studied in male rats aged 11-14 weeks, with estimates of cell proliferation being made between 1200 and 1600 hr to avoid circadian and gerontological variations in crypt cell proliferation. Two subgroups of rats were studied in each experiment: 1 subgroup used for cell cycle time studies was given i.p. injections of colchicine (0.1 mg/100 g) and killed after intervals of 1-4 hr; the 2nd subgroup used for estimating mitotic time did not receive colchicine injections. Small doses of serotonin (10 μg/kg i.p.) shortened crypt cell cycle time, whereas very large doses (300 mg/kg) prolonged both cell cycle time and mitotic time. Partial serotonin depletion following injection of 6-fluorotryptophan (1.5 mM/kg i.p.) retarded crypt cell cycle and mitotic time. The experimental results offer an explanation for elevated urinary levels of serotonin metabolites observed in patients with celiac disease. Increased cell proliferation observed in this disease may be mediated *via* an increase in the rate of serotonin from enterochromaffin cells of the small intestine.

7622 THE RESPONSES OF RAT INTESTINAL BRUSH BORDER AND CYTOSOL PEPTIDE HYDROLASE ACTIVITIES TO VARIATION IN DIETARY PROTEIN CONTENT: DIETARY REGULATION OF INTESTINAL PEPTIDE HYDROLASES.

(E.) Nicholson, J. A.; McCarthy, D. M.; Kim, Y. S. (VA Hosp., San Francisco, Calif.). *J. Clin. Invest.* 54(4):890-898, 1974.

The effects of variation in dietary protein content on small intestinal brush border and cytosol peptide hydrolase activities were investigated using male Wistar rats. One group of rats was fed a high protein diet (55% casein) and another was fed a low protein diet (10% casein). After 1 week, brush border peptide hydrolase activity was significantly greater in rats fed the high protein diet when data for corresponding segments were compared. No significant difference was seen in cytosol peptide hydrolase activity. In a second study, brush border and cytosol peptide hydrolase activities were determined in the proximal intestine as were sucrase, maltase, and alkaline phosphatase activities. As before, brush border peptide hydrolase activities were significantly greater in rats fed the high protein diet. However, activities of the nonproteolytic brush border enzymes did not vary significantly with diet. It is suggested that the brush border peptide hydrolase response to variation in dietary protein content represents a functional adaptation analogous to the regulation of intestinal disaccharidases by dietary carbohydrates.

7623 DIRECT MEASUREMENT OF GASTRIN RELEASE FROM DUODENUM AND JEJUNUM IN DOGS. *(E.)*

Becker, H. D.; Reeder, D. D.; Thompson, J. C. (Univ. Texas Med. Branch, Galveston). *Am. J. Physiol.* 227(4): 897-900, 1974.

The release of gastrin from the duodenum and jejunum of dogs stimulated by locally applied agents was investigated. Serum gastrin concentrations were measured directly by radioimmunoassay in the venous outflow draining the segment of intestine being studied. Perfusion of the proximal duodenum with 0.5% acetylcholine (Ach) pH 7.0, saline pH 7.0, or 0.4 M glycine pH 7.0 caused a significant release of gastrin. Perfusion of the distal duodenum with any of these agents did not cause a release of gastrin. Perfusion of the jejunum with 0.5% Ach pH 7.0 caused a prompt increase of serum gastrin concentration in the venous outflow. The gastrin concentrations achieved by perfusion of the jejunum with Ach, however, were about 70% lower than during perfusion of the proximal duodenum. The results provide evidence that the release of gastrin from the duodenum is pH dependent, since in all experiments lowering of pH caused an immediate decrease in levels of stimulated gastrin in the venous outflow. The results also suggest that Ach is a specific stimulus for the release of gastrin since there was no increase in serum cholecystokinin (as measured by radioimmunoassay).

7624 SUPPRESSOR CELLS IN THE RABBIT APPENDIX.

(E.) Kamin, R. M.; Henry, C.; Fudenberg, H. H. (Dept. Bacteriol. Immunol., Univ. California, Berkeley). *J. Immunol.* 113(4):1151-1161, 1974.

Rabbit appendix cells added to cultures of spleen cells, primed *in vivo* to sheep red blood cells, horse red blood cells, or azo-phenyl β-lactoside-keyhole limpet hemocyanin suppressed the secondary *in vitro* response of the spleen cells to the test antigen. Although suppression of both the IgG and IgM responses could be demonstrated when appendix cells were added at the onset of culture or 24 hr after culture initiation, suppression of the IgM response was less when appendix cells were added 48 hr after culture initiation. Two lines of evidence indicate that a T-cell population was involved in the suppression observed. Suppressor cell activity was also found in spleen and Peyer's patches. The observation that normal cell populations of appendix, spleen, and Peyer's patches were capable of suppressing the secondary *in vitro* response to azo-phenyl β-lactoside indicates a general rather than an antigen-specific suppression. It is proposed that the suppressor activity of the appendix may be a key function of this organ.

7625 X-RADIATION-INDUCED INTESTINAL LESIONS IN PROTEIN-DEFICIENT RATS. *(E.)* Deo, M. G.; Verma, K.; Ramalingaswami, V. (All-India Inst. Med. Sci., New Delhi). *Arch. Pathol.* 98(4):269-273, 1974.

Morphologic alterations in the jejunum following a single dose of 200 rads whole-body or 650 rads focal x-radiation to the abdomen were studied in protein-deficient rats and pair-fed controls. A similar study was also made in animals fed a stock diet but having weights similar to those of the protein-deficient animals at the time of x-radiation. A total of 133 young, male albino rats, weighing from 35 to 50 g, were used in the investigation. The protein-deficient animals showed less cellular degeneration, necrosis, and inflammatory response when compared with the controls. Recovery as judged by the rate of reappearance of mitoses was slow in the deficient animals. The jejunal crypts of the deficient animals contained a higher number of megalocytes when compared with the number found in the controls, following focal x-radiation. These observations suggest that higher susceptibility of the protein-deficient host is probably due to poor regeneration and not to increased sensitivity of the deficient tissues to x-radiation.

7626 A COMPARISON OF STOOL FLUID AND STOOL DIALYSATE OBTAINED IN VIVO. *(E.)* Tarlow, M. J.; Thom, H. (Dept. Child Hlth., Univ. Aberdeen, Scotland). *Gut* 15(8):608-613, 1974.

Stools were collected from 2 healthy adult volunteers who produced rather soft stools. Stool fluid was obtained by freezing and thawing, homogenization, and high-speed centrifugation. This fluid was compared with stool dialysate obtained *in vivo* from the same individuals by retrieval of swallowed dialysis bags from their stools. Stool fluid was more acidic, and had a higher osmolality, an increased concentration of organic anions, sugar and ammonia, and a lower bicarbonate concentration than dialysate *in vivo*. The difference in composition between stool fluid and stool dialysate cannot be accounted for by artifacts of the handling technique nor by continued fermentation of stool after passage. Therefore, it is suggested that in the individuals studied stool dialysate *in vivo* may not be in equilibrium with the stool fluid surrounding it and may not represent a true dialysate of the extracellular component of fecal water.

7627 NEURONAL AND MUSCULAR ACTIONS OF CYCLIC AMP (cAMP) AND DIBUTYRYLCYCLIC AMP (db cAMP) IN GUINEA PIG ILEUM AND VAS DEFERENS. *(E.)* Wikberg, J. (Sch. Med., Linkoping, Sweden). *Acta Pharmacol. Toxicol. [Suppl.] (Kbh.)* 35:56, 1974.

GENERAL

7639 VASCULAR RESPONSIVENESS OF THE IN SITU PERFUSED DOG PANCREAS. *(E.)* Gorczynski, R. J.; Spath, Jr., J. A.; Lefer, A. M. (Univ. Virginia Sch. Med., Charlottesville). *Eur. J. Pharmacol.* 27 (1):68-77, 1974.

The dog pancreas, perfused *in situ*, was used to study: (1) the role of humoral vasoactive agents in maintaining pancreatic hypoperfusion in shock, (2) the mechanisms involved in the protective action of glucocorticoids in shock, and (3) pancreatic vascular response to ouabain. Close intra-arterial injection of norepinephrine (4 ng/ml), epinephrine (10 ng/ml), vasopressin (0.3 mU/ml), and angiotensin (5 ng/ml), concentrations present in animals with hemorrhagic shock, significantly increased pancreatic vascular resistance. Bradykinin (5 ng/ml), prostaglandin E_1 (30 ng/ml) and prostaglandin E_2 (75 ng/ml) exerted a vasodilator effect. The glucocorticoids, methylprednisolone (1 mg/kg intra-arterial, 30 mg/kg, i.v.) and dexamethasone (0.2 mg/kg intra-arterial and 8 mg/kg i.v.) were without net vascular effect in the perfused pancreas at these concentrations, which are comparable to those known to be protective in hemorrhagic shock. Ouabain (12.5 μg/kg) produced a persistent increase in pancreatic vascular resistance. These results indicate that the pancreas is responsive to vasoactive agents which are released in hemorrhage. The responsiveness to these agents is influenced by the blood flow to the organ. When blood flow is decreased, response to a vasoconstrictor is enhanced and response to a vasodilator is diminished. The failure of i.v. glucocorticoids to cause changes in the pancreatic perfusion pressure or systemic arterial pressure indicates that these glucocorticoids do not have a significant vasodilator action and suggests other mechanisms must be considered to explain their protective action in hemorrhagic shock. The ability of ouabain to produce vasoconstriction in the pancreatic vasculature suggests that ouabain might be used to treat shock states.

7640 GASTRIC MUCOSAL BLOOD FLOW MEASUREMENT. *(E.)* Sales, J.; Bickel, J.; Norton, L.; Eiseman, B. (Denver Gen. Hosp., Colorado). *J. Surg. Res.* 17(3):171-176, 1974.

Pertechnetate clearance by the stomach before and after betazole stimulation was compared to regional measurements of gastric blood flow utilizing ^{51}Cr- or ^{141}Ce-labeled microspheres in five piglets. Pertechnetate clearance closely correlated with mucosal blood flow in the gastric corpus measured by the microsphere technique. Betazole increased blood flow in the corpus region by 100% but did not alter this relationship. Except in one experiment, microsphere blood flow values in the antrum and fundus were unchanged by betazole and did not significantly correlate with pertechnetate clearance. Pertechnetate clearance appears to be a reliable method of determining gastric mucosal blood flow in experimental animals and may be considered as a noninvasive method for measuring such flow in humans.

DIAGNOSTIC PROCEDURES

7647 PERORAL JEJUNAL MUCOSAL BIOPSY IN DERMATOLOGICAL AND SOME NON-DIARRHEAL DISEASES. *(E.)* Madanagopalan, N.; Shantha, M.; Rao, U. P.; Thambiah, A. S. (Madras Med. Coll., India). *Australas. J. Dermatol.* 14(1):47-52, 1973.

The dissection microscopic and light microscopic appearance of the jejunal mucosa in various dermatological disorders and in a few nondiarrheal diseases without significant alimentary symptoms were studied in biopsies. The dermatological disorders studied included psoriasis (14 cases), pemphigus (6), Darier's disease (5), scleroderma (2), and one case each of Bockhardt's impetigo and acne rosacea. Patients with nondiarrheal diseases included those with diabetes mellitus (7), chyluria (5), lymphoma (5), syphilis (2), Hurler's syndrome (1), and traumatic paraplegia (1). On dissection microscopy, mucosa was classified as Grade I, predominant fingers; Grade II, predominant leaves; Grade III, predominant convolutions, or Grade IV, flat. The appearance at light microscopy was classified as normal, partial villous atrophy, or subtotal villous atrophy. Of the 14 cases of psoriasis, predominant Grade III changes were observed in 9 and predominant Grade II changes in 5. No Grade IV changes were seen. In 10 cases of psoriasis, the light microscopic appearance was partial villous atrophy. The incidence of abnormalities in psoriasis was significantly higher than that of the other skin diseases studied; moreover, the incidence of Grade III changes was higher than that previously reported for diarrheal diseases in the local population (Madras). In nondiarrheal diseases, Grade III changes and partial villous atrophy each occurred in 3 cases of diabetes mellitus and 3 cases of lymphoma. In view of the extent of abnormal villous morphology in the local population, the mucosal abnormalities in these patients with skin disease may not be significant. However, patients with psoriasis are likely to show greater abnormalities than patients with other dermatological diseases.

7648 USEFULNESS OF SERIAL SERUM CARCINOEMBRYONIC ANTIGEN (CEA) DETERMINATIONS DURING ANTICANCER THERAPY OR LONG-TERM FOLLOWUP OF GASTROINTESTINAL CARCINOMA. *(E.)* Ravry, M.; Moertel, C. G.; Schutt, A. J.; Go, V. L. W. (Mayo Clin., Rochester, N.Y.). *Cancer* 34(4):1230-1234, 1974.

Serial measurements of carcinoembryonic antigen (CEA) were made on 30 asymptomatic, untreated patients (controls) with unresectable gastrointestinal cancer; on 57 symptomatic patients before and during chemotherapy for unresectable gastrointestinal cancer; and on 80 patients who had undergone resection for colorectal cancer. In 19 controls followed for a 20-day period, CEA values were elevated initially and showed day-to-day variations of ± 35%. In the 11 controls followed for 6 months, CEA was abnormal initially (>2.5 mg/ml) and rose progressively through the study period, the rise correlating with clinical evidence of progressive disease. Prechemotherapy CEA levels were abnormal in 42 patients. Thirteen (65%) of 20 who showed objective clinical progression had a corresponding increase in CEA, while 6 (75%) of 8 patients with objective improvement had a corresponding decrease in CEA. No change in serum CEA occurred in 8 clinically stable patients. Paradoxical reductions in CEA levels occurred in 4 patients approaching terminal status. In 15 patients CEA levels were normal prior to chemotherapy. In 4 with clinically progressive disease, CEA correspondingly rose to abnormal levels. However, CEA levels remained unchanged in 10 of the remaining 11 patients, including 4 with obvious progression of disease. Of the 80 patients followed after potentially curative resection of large intestine cancer, all had normal postoperative CEA levels. Six again have clinical evidence of malignant disease and in 5 of these there was a concurrent elevation of serum CEA. Serial serum CEA determinations apparently have some value for following the course of gastrointestinal cancer patients after surgery or chemotherapy, but these determinations must be interpreted in the context of the overall clinical picture.

7649 DEMONSTRATION OF PORTOCAVAL [SIC!] SHUNTS AND SUPERIOR MESENTERIC VENOUS COLLATERAL CHANNELS FOLLOWING SELECTIVE INTRA-ARTERIAL INJECTION OF VASODILATORS. *(E.)* Redman, H. C. (Wayne County Gen. Hosp., Eloise, Mich.). *Invest. Radiol.* 9(3): 199-204, 1974.

Vasodilators including bradykinin (1.0-10.9 mg), tolazoline (5-10 mg), eledoisin (0.5-5.0, 10.0 μg), epinephrine (2.0-6.0 μg), glucagon (5-20 μg), acetylcholine (0.5-1.0, 5 mg), meglumine diatrozoate (12 ml of a 76% solution), histamine (0.01-0.1 mg), and papaverine (10-60 mg) were selectively injected into the superior mesenteric artery in dogs with end-to-side portacaval shunts. Angiograms were performed before and after administration of the vasoactive drugs to show any changes in arterial, capillary, and venous phases. Bradykinin and glucagon caused the most improvement in venous visualization. Tolazoline and, to a lesser extent, meglumine diatrozoate, also consistently enhanced venous visualization. Eledoisin produced a moderate to marked improvement at the lower doses; the highest dose was associated with hypotension and decreased visualization. The remaining drugs caused a lesser, inconsistent response. Although unavailable for clinical use in the United States, bradykinin is the best drug for improving venous visualization in both dog and man. The improvement caused by bradykinin was associated with decrease in arterial detail, decreased aortic reflux, and early venous appearance. No systemic effects were noted.

7650 THE JOINT NATIONAL CANCER INSTITUTE OF CANADA/AMERICAN CANCER SOCIETY STUDY FOR CARCINOEMBRYONIC ANTIGEN (CEA). *(E.)* Miller, A. B. (Natl. Cancer Inst., Toronto, Canada). *Cancer* 34(3): 932-935, 1974.

The usefulness of testing for carcinoembryonic antigen (CEA) as a diagnostic procedure for cancer was evaluated in 503 patients, 146 of whom had cancer of the colon or rectum. Positive results (2.5 ng/ml CEA or more) occurred in 62% of the preoperative specimens from colorectal cancer patients. Of the patients with colorectal cancer, 58% of those with Dukes' B2 and C1 lesions and 83% of those with advanced lesions (C2) were positive for CEA. In contrast, the test was positive in only 28% of colorectal cancer patients with minimal lesions, Dukes' A and B1. This low positivity rate in patients with less advanced disease is a disappointing feature of the test. Positive results occurred in 53% of the specimens from patients with cancer elsewhere in the gastrointestinal tract as well as in the breast and lung, and in 29% of those with other diagnoses, usually gastrointestinal complaints. It is concluded that, although the test shows promise as a diagnostic aid for colorectal cancer, its lack of specificity precludes its use for screening.

GASTROINTESTINAL DISEASES

ESOPHAGUS

7694 EPIDERMOLYSIS BULLOSA: GASTROINTESTINAL MANIFESTATIONS. *(E.)* Orlando, R. C.; Bozymski, E. M.; Briggaman, R. A.; Bream, C. A. (Univ. North Carolina Sch. Med., Chapel Hill). *Ann. Intern. Med.* 81:203-206, 1974.

Dysphagia and clinically apparent esophageal involvement were studied in association with epidermolysis bullosa dystrophica (recessive) in 8 patients (6 males and 2 females, aged 6-21 yr). In this group of 8, siblings of 3 families were afflicted with epidermolysis bullosa dystrophica, and only 1 patient had no affected siblings. The inheritance system was consistent with an autosomal recessive pattern. Dysphagia was the major esophageal symptom in all cases and had been present from 3-21 yr, with a mean of 11.25 yr. Blenderized diets alleviated the symptoms. Barium studies revealed 7 patients with esophageal strictures from 2 mm to 7 cm long; 4 strictures were located in the upper third of the esophagus, 2 in the middle third, and 1 involved the middle and lower third. Length of stricture did not correlate with duration of symptoms. One to 7 yr after their initial study, repeat esophagrams in 4 patients showed no changes in the strictures. Manometric and radiologic studies showed 4 patients with predisposition for gastrointestinal reflux. While 2 of the 4 had a history of heartburn and 2 had an incompetent lower esophageal sphincter, none had lower esophageal strictures. The 1 patient with such a stricture had no heartburn and a negative study for reflux. Thus, the findings do not support the concept that strictures in the lower third of the esophagus reflect increased mucosal damage from reflux of gastric acid. Trauma may be a factor in lower as well as in upper esophageal strictures. Constipation with fecal impaction was a significant problem in 7 patients with dermolysis bullosa dystrophica (recessive). Since the symptoms and strictures were not progressive, conservative management of patients with dysphagia is advocated.

7695 MEASUREMENT OF PRESSURE IN THE LOWER ESOPHAGEAL SPHINCTER: THE INFLUENCE OF CATHETER DIAMETER. *(E.)* Kaye, M. D.; Showalter, J. P. (Univ. Vermont Med. Coll., Burlington). *Am. J. Dig. Dis.* 19(9):860-863, 1974.

Manometric assessments of the lower esophageal sphincter (LES) were performed on 10 healthy individuals (9 male and 1 female, mean age 28.7 yr) with two separate perfused catheter systems differing only in their external diameters (3.2 *versus* 7 mm) to assess the relation between catheter diameter and the LES functions of maximum resting pressure and relaxation in response to deglutition. Continuous pull-through measurement of maximum resting pressures was 17.7 ± 5.6 mm Hg for the large catheter compared with 12.5 ± 4.3 mm Hg for the smaller catheter. End-expiratory, end inspiratory, and mid-respiratory station withdrawal measurements with the large catheter were 14.3 ± 6.6, 17.9 ± 8.3, and 16.1 ± 7.2, resp., compared with 9.6 ± 3.6, 12.6 ± 4.7, and 11.1 ± 4.0 for the small catheter. Residual pressures during postdeglutitive relaxation were similar with the two systems. The observations show that LES pressures recorded with perfused catheters are in fact measurements of the resistance to stretch of sphincteric smooth muscle. In situations where relaxation of the sphincter is not normal, e.g., achalasia, the degree of relaxation recorded might well decrease as catheter size increases.

7696 GASTRIC ALKALINIZATION: EFFECT ON LOWER-ESOPHAGEAL-SPHINCTER PRESSURE AND SERUM GASTRIN. *(E.)* Higgs, R. H.; Smyth, R. D.; Castell, D. O. (U.S. Naval Hosp., Philadelphia, Pa.). *N. Engl. J. Med.* 291(10):486-490, 1974.

The increase in lower esophageal sphincter pressure after gastric alkalinization has been attributed to endogenous gastrin release. The sphincter response to 4 different alkalinizing agents and serum gastrin levels were compared in 10 normal men (aged 19-35 yr); the agents were sodium bicarbonate (3.4 g), calcium carbonate (2.0 g), magnesium hydroxide and aluminum hydroxide (15 ml), and magnesium hydroxide and aluminum hydroxide combined with calcium carbonate (11 ml). In addition, calcium carbonate (2.0 g) was given to 5 men (aged 23-41 yr) with peptic ulcer disease. In the 10 normal subjects, the serum gastrin levels did not change significantly in response to gastric alkalinization, despite increases in sphincter pressure. The serum gastrin levels and lower esophageal sphincter pressure decreased after 30 min of gastric acidification (0.1 *N* hydrochloric acid). Although the pressure increased with subsequent gastric alkalinization, the serum gastrin levels did not change from the depressed postacidification levels. In the five patients with peptic ulcer disease, calcium carbonate increased sphincter pressure at a time when the serum gastrin levels were unchanged. When the serum gastrin levels did increase, the sphincter pressure returned to basal levels. The data confirm the elevating effect of gastric alkalinization on the sphincter pressure, but suggest that endogenous gastrin release has little, if any, role in this response.

7697 MEASUREMENTS AND COMPARISONS OF LOWER ESOPHAGEAL SPHINCTER PRESSURES AND SERUM GASTRIN LEVELS IN PATIENTS WITH GASTROESOPHAGEAL REFLUX. *(E.)* Farrell, R. L.; Castell, D. O.; McGuigan, J. E. (Univ. Florida Coll. Med., Gainesville). *Gastroenterology* 67(3):415-422, 1974.

Serum gastrin levels and lower esophageal sphincter pressures were studied in 10 normal men (aged 20-73 yr) and in 12 patients (10 men and 2 women, aged 19-75 yr) with symptoms and radiographic evidence of chronic gastroesophageal reflux. Following ingestion of a 100-g lean roast beef meal, mean lower esophageal sphincter pressure increased in both control and symptomatic patients, but the rate of increase and the peak pressure were consistently significantly less in reflux patients. Mean serum gastrin levels showed a similar pattern of transient increase, reaching a peak in both groups after 30-45 min, but being significantly higher in control patients only after 45 min. Mean lower esophageal sphincter pressures and mean serum gastrin levels in control and reflux patients showed a significant decrease from basal levels following gastric acidification as well as a significant increase following alkalinization. At all times, sphincter pressure and serum gastrin levels were less in the reflux group than in the control group. Sphincter pressure increases following i.v. pentagastrin infusion were significantly greater in control subjects compared with reflux patients. These results suggest a role for gastrin deficiency in the incompetent lower esophageal sphincter.

7698 HYPOGASTRINEMIA IN PATIENTS WITH LOWER ESOPHAGEAL SPHINCTER INCOMPETENCE. *(E.)* Lipshutz, W. H.; Gaskins, R. D.; Lukash, W. M.; Sode, J. (Natl. Naval Med. Ctr., Bethesda, Md.). *Gastroenterology* 67(3):423-427, 1974.

The effect of gastric alkalinization and gastric instillation of glycine on lower esophageal sphincter pressure was studied in 9 patients with and 8 patients without symptomatic gastroesophageal reflux. Gastric acidity was titrated to pH 4 to 6 with 0.1 N NaOH; 1.5% glycine (180 ml) was then infused intragastrically at a rate of 30 ml/min. Serum gastrin levels were monitored periodically by radioimmunoassay and lower esophageal sphincter pressures were correlated. In normal subjects, lower esophageal sphincter pressure increased, following infusion of alkali and glycine, to 200% of the basal pressure. Sphincter pressure in symptomatic patients increased by only 36%. Mean fasting serum gastrin levels were decreased in patients with reflux. Peak serum gastrin levels following alkali and glycine infusion were over 2 times as high in normal subjects compared with symptomatic patients. These results lend support to the concept that gastrin is an important determinant of lower esophageal sphincter pressure, and suggest that hypogastrinemia may contribute to the pathogenesis of lower esophageal sphincter incompetence in humans.

7699 CORRELATION BETWEEN A PHYSIOLOGICAL TEST OF GASTRO-OESOPHAGEAL REFLUX AND SPHINCTER SQUEEZE. *(E.)* Stanciu, C.; Bennett, J. R. (Hull Roy. Infirm., Kingston upon Hull, England). *Proc. Int. Symp. Gastrointest. Motility, 4th, 1973* pp. 131-138.

Symptoms of gastroesophageal reflux, measured by lower esophageal pH over a 15-hr period, and lower esophageal sphincter pressure, measured by a catheter perfusion technique, were studied in 42 normal subjects and 200 patients with symptoms of gastroesophageal reflux. Mean resting end-expiratory sphincter pressure of normal subjects was 18.0 ± 7.3 cm H_2O and was significantly higher than that of the patients with reflux symptoms (12.2 ± 7.9 cm H_2O). Reflux (i.e., decreased intraesophageal pH) correlated with reflux symptoms. There was, however, no correlation between sphincter pressure and the number of reflux episodes, between sphincter pressure and mean duration of reflux episodes, or between sphincter pressure and the length of time in which esophageal pH was less than pH 5, 4, or 3. Thus, pH studies appear to be more reliable and reproducible than measurements of sphincter pressure in assessing gastroesophageal reflux.

7700 GASTRIN AND GASTROESOPHAGEAL SPHINCTER INCOMPETENCE. *(E.)* Kun, T. L.; Sturdevant, R. A. L. (Wadsworth Hosp., Los Angeles, Calif.). *Proc. Int. Symp. Gastrointest. Motility, 4th, 1973* pp. 125-130.

Gastroesophageal or lower esophageal sphincter (LES) pressure was studied by manometry in the resting state and after graded i.v. doses of pentagastrin (0.1 to 0.8 μg/kg at 10 min intervals) in 10 patients with gastroesophageal reflux and in 21 control subjects. Mean basal LES pressure and peak LES pressure response to pentagastrin in the reflux patients was significantly lower than in the control subjects. Mean basal and peak meal-stimulated serum gastrin levels, were not significantly different in 8 of 10 reflux patients compared with 7 of the 21 normal subjects. These data do not support the hypothesis that the basic pathophysiological mechanism of low LES pressure in reflux patients is decreased serum gastrin.

7701 THE PROBABILITY OF SYMPTOMS OR OF RADIOGRAPHIC EVIDENCE OF REFLUX PREDICTED BY LOWER OESOPHAGEAL SPHINCTER PRESSURE. *(E.)* Dilawari, J. B.; Edwards, D. A. W.; Girmes, D. H. (Central Middlesex Hosp., London, England). *Proc. Int. Symp. Gastrointest. Motility, 4th, 1973* pp. 441-448.

The possible role of lower esophageal sphincter (LES) pressure as a predictor of the probability of symptoms or the presence of radiographic reflux was investigated by perfusion manometry in 246 subjects. Each of 4 tubes recorded a different pressure profile of the sphincter, apparently related to orientation of the side hole. Maximum sphincter pressure recorded by each tube was different, enabling calculation of sphincter pressure by 6 methods. Subjects with radiographic reflux had the same distribution of LES pressures as those without reflux, except that no reflux was seen in subjects with pressures above 18 mm Hg, which may represent the upper limit of challenge to the sphincter during the radiographic examination. The subjects without radiographic reflux, but with LES pressures below this critical level, must have had an additional anti-reflux mechanism. The difference in pressure between esophagus and fundus, recorded by a differential manometer during radiographic examination, was about 10 mm Hg. The frequencies of pressures appeared to fit log normal better than normal distributions. The probability of symptoms, deduced from the LES pressure, was unhelpful in diagnosis or management because of the considerable overlap in the distributions.

7702 PRIMARY DISORDERED MOTOR ACTIVITY OF THE ESOPHAGUS (DIFFUSE SPASM). DIAGNOSIS AND TREATMENT. *(E.)* Henderson, R. D.; Ho, C. S.; Davidson, J. W. (Univ. Toronto Fac. Med., Canada). *Ann. Thorac. Surg.* 18(4):327-336, 1974.

To delineate the diagnostic features of primary disordered motor activity (PDMA) of the esophagus, 21 patients with the disorder were studied clinically, roentgenographically, manometrically, and by esophagoscopy. All patients reported pain; dysphagia was present in 20; and weight loss occurred in 12. At the initial roentgenographic examination, the diagnosis of PDMA was made in only 5 patients. In a retrospective review of all high-quality roentgenograms, a specific diagnosis was possible in 8 of 11 patients on the basis of a combination of mural thickness and motor spasm. Manometry showed a very severe motor disorder in the lower 2/3 of the esophagus and, in conjunction with clinical and roentgenographic features, enabled a specific preoperative diagnosis to be made in 17 of the 21 patients. In 2 patients the misdiagnosis of associated hiatal hernia was corrected at operation by the finding of marked esophageal muscular hyperplasia and spasm. These pathological features were found in all patients at operation. In 2 patients with a food-retaining esophagus, preoperative manometry could not distinguish between achalasia and PDMA. Postoperative manometry made the distinction possible as proximal esophageal peristalsis was more recognizable. A myotomy from the stomach to 10 cm above the aortic arch was performed, but addition of a Collis gastroplasty was necessary to control reflux. With this approach 19 of 21 patients have been free of pain and dysphagia for 3-45 months.

7703 NORMAL LOWER-ESOPHAGEAL-SPHINCTER FUNCTION AFTER SURGICAL TREATMENT OF GASTROESOPHAGEAL REFLUX. *(E.)*

Lipshutz, W. H.; Eckert, R. J.; Gaskins, R. D.; Blanton, D. E.; Lukash, W. M. (Natl. Navy Med. Ctr., Bethesda, Md.). *N. Engl. J. Med.* 291(21):1107-1110, 1974.

To evaluate operations for gastroesophageal reflux, findings in 8 patients who underwent the Hill transabdominal gastropexy were compared with those in 7 patients who underwent the Belsey Mark IV transthoracic repair. Of the 15 patients, 12 had hiatus hernia, 11 free gastroesophageal reflux of barium, and 10 peptic esophagitis. Two months to 4 yr after surgery all but 1 of these abnormalities disappeared in 14 patients, who were also asymptomatic. Lower esophageal sphincter pressure increased from 5.4 ± 0.4 mm Hg to 16.5 ± 1.0 after the Hill repair and to 12.12 ± 1.3 after the Belsey repair. The difference between the preoperative and postoperative values was highly significant. Similar improvement marked the response to abdominal compression; peak sphincter response to pentagastrin (0.5 μg/kg i.v.) increased from 17.2 ± 3.7 mm Hg to 35.5 ± 2.9 after the Hill repair and 41.7 ± 7.9 after the Belsey repair. The differences between pre- and postoperative values were significant. Both operations resulted in clinical improvement and lower esophageal sphincter function that appeared essentially normal.

7704 ENZYME AND ULTRASTRUCTURAL CHARACTERISTICS OF ESOPHAGEAL COLUMNAR EPITHELIUM. *(E.)*

Berenson, M. M.; Herbst, J. J.; Freston, J. W. (Univ. Utah Med. Ctr., Salt Lake City). *Am. J. Dig. Dis.* 19(10):895-907, 1974.

A unique columnar epithelium with elaborate microvilli, secretory granules, and inability to absorb lipid lines the distal esophagus in many patients with midesophageal stricture. To clarify the nature and derivation of this epithelium, specimens from 3 patients with midesophageal stricture and 1 with an esophageal (Barret's) ulcer were studied by electron microscopy, enzyme histochemistry, and specific disaccharidase assay. The ultrastructure of the columnar epithelium was similar in all 4 patients. The principal cells had well-developed microvilli on the apical surface with a glycocalyx and incompletely formed terminal webs. Intercellular spaces between the lateral borders of many of these cells were greatly distended with a floccular material. Spherical bodies were interspersed between the microvilli; spherical and ellipsoid secretory granules were present in the apical cytoplasm. The secretory granules were homogenous, stippled, and unevenly dense. The epithelial tissue lacked disaccharidase activity. Membrane-related enzymes (alkaline phosphatase, glucose-6-phosphatase, and leucine aminopeptidase) located primarily on the brush border and lysosomal-membrane enzymes (acid phosphatase and 5-nucleotidase) were substantially less than in normal intestine but more active than in gastric tissue. The dissociation of structural and functional characteristics suggest a metaplastic derivation of this tissue.

7705 THE PATTERN OF BILE SALT REFLUX AND ACID SECRETION IN SLIDING HIATAL HERNIA. *(E.)*

Crumplin, M. K. H.; Stol, D. W.; Murphy, G. M.; Collis, J. L. (Queen Elizabeth Hosp., Birmingham, England). *Br. J. Surg.* 61(8):611-616, 1974.

The role played by gastric fluid refluxed from the stomach into the esophagus of 23 patients with symptomatic sliding hiatal hernia was evaluated in terms of gastric bile salt concentration and acid secretion rate. The patients included 13 with heartburn and esophagitis and 10 with a peptic stricture. Basal acid output was significantly higher in patients with a peptic stricture than in 15 controls. Approximately 1/2 of both hiatal hernia groups had periods of increased bile salt concentrations while fasting or following a test meal. This would indicate abnormal pyloric function in these patients. No unusual conjugates or free bile acids were detected in individual bile salt studies. The glycine/taurine conjugate ratio was markedly reduced in samples with a pH less than 4.5 compared with the ratio in duodenal bile with a normal alkaline pH. Since the stricture group had a substantial basal acid output in view of the mean age of the group (63.5 ± yr), it is postulated gastric acid pepsin and taurine conjugates bathe the lower end of the esophagus at night and between meals. The esophageal mucosa of these patients could be unduly sensitive to this combination. Increased pyloric reflux in approximately 1/2 the hiatal hernia patients suggests that a combination of gastric acid pepsin and bile is a major factor in the pathogenesis of the clinical responses to gastroesophageal reflux. Neither total nor individual bile salt concentrations in gastric juice helped to differentiate between the responses seen in symptomatic sliding hiatal hernia.

7715 ARE PEPSINOGENS ACTIVATED IN GASTRIC MUCOSA AFTER ASPIRIN-INDUCED INJURY? *(E.)* Mangla, J. C.; Kim, Y. M.; Turner, M. D. (Monroe Community Hosp., Rochester, N.Y.). *Experientia* 30(7): 727-729, 1974.

The possibility that pepsinogens in gastric mucosa are activated to pepsins after aspirin-induced injury was investigated in 20 male Holtzman rats given a single i.m. injection of aspirin (600 mg/kg) suspended in 1% methyl cellulose. From 5-15 mucosal erosions were seen in animals sacrificed 1 hr later; at 2 hr there were 10-25 erosions and at 3 hr, 10-30. Agar gel electrophoresis for the simultaneous demonstration of pepsinogens and pepsins in mucosal homogenates showed no differences in patterns in 1-3 hr samples from the 20 experimental and the 20 control animals. Thus, there was no evidence of *in vivo* activation of pepsinogens to pepsins. On agar gel electrophoresis at pH 5.7, mucosal homogenates from normal and aspirin-treated rats showed 4 major bands of proteolytic activity. After normal mucosal homogenates were acidified *in vitro* with 0.2 N HCl, the 4 bands were replaced by 3 bands of proteolytic activity with markedly enhanced mobility. None of the 20 mucosal homogenates from experimental animals showed 3 bands of proteolytic activity corresponding in mobility to the bands in the *in vitro* acidified mucosa. Incubation of normal mucosa in unbuffered aspirin resulted in proteolytic activity similar to that observed after treatment of the mucosa with HCl. Electrophoresis of acid activated mucosal homogenates at pH 8.3 gave only 1 band of residual proteolytic activity, the other 2 bands having been destroyed by the high pH. On electrophoresis at pH 8.3, mucosal homogenates from rats with aspirin-induced erosions still showed the 4 major bands of proteolytic activity, indicating that the bands were due to the presence of zymogens. One of the 4 zymogens may resemble the zymogen of human gastric mucosal cathepsin which is resistant to destruction on acid activation and subsequent neutralization. The results indicate that rat pepsinogens differ from human gastric mucosal pepsinogens. Unlike human pepsinogens, which did not coagulate milk even after 2 min, rat pepsinogens coagulated milk after 2 min of incubation. However, the disappearance of 2 components from the mucosal homogenates confirmed that acidification of the pepsinogens resulted in their activation to pepsins.

7716 THE DISTRIBUTION OF GASTRITIS IN CARCINOMA OF THE STOMACH. *(E.)* Du Plessis, D. J. (Johannesburg Hosp., South Africa). *Br. J. Surg.* 61(7):521-523, 1974.

Using the Swiss-roll technique, histological studies of the wall structure were performed on stomachs resected from 21 patients with carcinoma. Chronic gastritis with epithelial hyperplasia was present in all cases. The distribution of chronic gastritis varied and 2 types were clearly recognizable. In 17 cases, chronic gastritis extended continuously from the pylorus up to or beyond the carcinoma and in some cases involved the entire resected stomach. This type of gastritis could be due to reflux of duodenal contents into the stomach. Intestinal metaplasia was present in all 17 cases, and the carcinoma was in the distal part of the stomach in 14. In 4 stomachs, gastritis occurred in the vicinity of the carcinoma only, with no extension to the pylorus, and therefore could not be the result of duodenal reflux. Intestinal metaplasia was present in 2 of these 4 cases, and the carcinoma was in the distal stomach in 2. Two types of carcinoma of the stomach are postulated. One type is associated with the epithelial hyperplasia of chronic gastritis, possibly resulting from duodenal reflux. The other is also associated with chronic gastritis, but the cause of the gastritis is unknown.

7717 GASTRIC MOTILITY AND SERUM GASTRIN LEVELS IN CHRONIC ATROPHIC GASTRITIS. *(E.)*

Barbara, L.; Bortolotti, M.; Vezzadini, P.; Miglioli, M.; Labo, G. (1st Inst. Med. Pathol., Univ. Bologna, Italy). *Proc. Int. Symp. Gastrointest. Motility, 4th, 1973* pp. 153-164.

Studies to determine gastric emptying time and the myoelectrical and mechanical activity of the gastric antrum were conducted on 15 patients with chronic atrophic gastritis with hypergastrinemia (immunoreactive gastrin > 500 pg/ml), on 7 patients with chronic atrophic gastritis with normal or low serum gastrin levels (< 80 pg/ml), and on 9 normal subjects. In the first group with hypergastrinemia, gastric emptying time, basic electric rhythm (slow wave) frequency, and percent motor activity were significantly greater than these parameters in normal persons. Motility index (percent motor activity X mean wave amplitude) and mean wave amplitude were normal. In hypogastrinemic patients, gastric emptying time, basic electric rhythm, and percent motor activity were normal whereas motility index and mean wave amplitude were significantly less than normal. Radiologic studies confirmed normal peristaltic activity in hypergastrinemic patients and weak peristaltic waves in 4 of the 6 hypogastrinemia patients. Since the electrical and mechanical parameters of hypergastrinemic patients were similar to those seen during gastrin administration, which delays gastric emptying, it is felt that high serum gastrin levels may be involved in the delayed gastric emptying under these circumstances.

7718 GASTRIC CANCER IN AMERICAN NEGROES. *(E.)*

Kovi, J.; Viola, M. V.; Connolly, C. A.; Vohra, R. (Howard Univ. Coll. Med., Washington, D.C.). *Cancer* 34(3):765-770, 1974.

A retrospective study was conducted of 150 consecutive black patients (110 men and 40 women, aged 25-87 yr) with histologically confirmed gastric carcinoma. The most common presenting symptoms and the percentages of patients in whom they appeared were: pain (65.3%), weight loss (59.3%), cachexia (52.0%), vomiting (41.3%), anorexia (39.3%), nausea (22.0%), malaise (14.0%), early satiety (14.0%), epigastric mass (10.0%), Virchow's node (5.3%), and rectal shelf (2.0%). Associated gastrointestinal diseases included peptic ulcer (12 cases), second primary cancer of the colon or bladder (1 each), gastric polyps (4 cases), and pancreatitis (2). An upper gastrointestinal roentgenographic examination was performed on 82 patients and gave a positive diagnosis of cancer in 85.4% of the cases, indicating the advanced state of many of the cases in this series. Analysis of fasting gastric contents in 34 patients showed that in 94.1% free hydrochloric acid was absent or low and in 5.9% normochlorhydria was present. None of the patients had a history of pernicious anemia. In contrast to an excess of blood group A observed in predominantly white series, the black patients with gastric cancer had an excess of blood group B. In both males and females, diffuse carcinoma was predominant in the younger age groups. With advancing age, the incidence of well-differentiated adenocarcinoma significantly increased in both sexes. Surgical procedures included subtotal gastrectomy (34 patients), radical subtotal gastrectomy (40), total gastrectomy (10), bypass gastrojejunostomy (12), gastrostomy (5). The operability rate was 72.1% and the operative mortality was 18.8%. Median survival time according to the TNM staging system for patients with Stage I disease was 30 months; for Stage II, 12 months; Stage III, 3.5 months; and Stage IV, 2 months. The survival of black patients in each stage of disease was considerably poorer than for comparable white patients.

7719 STANDARDIZATION OF ELECTROSURGICAL LESIONS. *(E.)*

Blackwood, W. D.; Silvis, S. E. (Texas Tech. Univ. Sch. Med., Lubbock). *Gastrointest. Endosc.* 21(1):22-24, 1974.

An attempt was made to control the depth of tissue necrosis in the canine stomach by controlling amperage and application times of electrosurgical currents. The coagulation technique employed on 43 dogs consisted of passing a 2-mm round electrode tip through an Olympus GE-BK fibergastroscope, placed against the gastric mucosa under direct vision, and applying a bipolar radio-frequency current. A single lesion resulted from one current application. A double lesion resulted from two identical current applications, with the second superimposed on the first or at the edge of the initial lesion. A 1-cm lesion was obtained through multiple applications of current. The single application in the range of 400-425 mA for 1.0-1.5 sec caused mucosal necrosis with little or no muscle necrosis. Significantly increased muscle necrosis resulted from prolonging the time to 2.0 sec or increasing the current to 500 mA. Repeating the current application in the same or immediately adjacent location increased the depth of necrosis by 70-80%. Ulcers of about 1 cm diameter showed the least muscular necrosis with 1 sec applications of currents between 350 and 400 mA. Shortening the duration with a maximal power setting produced increased muscle necrosis even at the shortest interval tested, 0.4 sec. These results verify the difficulties in standardizing electrosurgical technics. The total power converted to heat is the ultimate determinant of the amount of tissue necrosis. Electrode contact is a major problem as are the changes caused in tissues by heating which result in changes in resistance and thus in current flow. It is advisable to maintain the current below 400 mA with applications of 1 sec or to set the coagulator at a moderate level and visually control the size of the coagulated area to 2-2.5 mm for each application. Data in this study apply only to the use of a 2-mm rounded electrode tip applied to a flat mucosal surface.

7720 POST-OPERATIVE GASTRIC ELECTRICAL CONTROL ACTIVITY (ECA) IN MAN.

(E.) Sarna, S. K.; Bowes, K. L.; Daniel, E. E. (Dept. Electr. Eng., Univ. Alberta, Edmonton, Canada). *Proc. Int. Symp. Gastrointest. Motility, 4th, 1973* pp. 73-83.

Gastric electrical control activity was recorded from 9 patients during and for 5 days following laparotomy (cholecystectomy, 7 patients; Nissen fundoplication and splenoctomy, 1; splenectomy and incidental cholecystectomy, 1). Three pairs of recording electrodes were implanted in the seromuscular layer of the anterior gastric wall near the greater curvature. The distal pair of electrodes was located 1-3 cm from the pylorus and the proximal pair 10-15 cm from the pylorus. The lead wires were brought out along with a Penrose drain and 4-5 days later were removed with the drain. During surgery, the mean gastric electrical control activity was 2.7 cycles/min. The control activity was regular in all patients. The direction of the lag phase was aborad. In all patients, the gastric electrical control activity became highly irregular 15-180 min following the closure of the abdomen. Frequently the control wave became unphase-locked. Phase locking with an orad direction of phase lag was occasionally seen. In 7 patients the frequency during this period decreased while in 2 patients it increased. Response activity (spikes) did not occur during the period of irregular frequencies. From 7-25 hr after surgery, the gastric electrical control activity in all patients became regular with a mean frequency of 3.2 cycles/min. The mean frequency was higher after recovery than during surgery in all patients. Response activity also occurred when the electrical control activity recovered fully. The results indicate the potential diagnostic value of the gastrointestinal electrical control activity. Abnormalities in this activity may be related to gastrointestinal motility disorders in certain pathological states.

7721 INTESTINAL METAPLASIA OF GASTRIC MUCOSA: ITS FREQUENCY AND FUNCTIONAL PROPERTIES.

(E.) Simon, L.; Figus, A. I. (Jaszbereny Hosp., Hungary). *Neoplasma* 21(4):455-463, 1974.

The frequency of intestinal metaplasia in an Hungarian population was determined by histological examination of 125 stomachs resected for gastric carcinoma, 106 stomachs resected for gastric ulcer, and biopsy material from 678 patients with chronic gastritis and from 96 unoperated patients with gastric ulcer. The frequency of intestinal metaplasia increased with age and the incidence was higher in patients with gastric cancer than in other patient groups. Lactic acid dehydrogenase activity in gastric juice increased in direct proportion to the severity of atrophic gastritis; activity was highest in patients with atrophic gastritis plus intestinal metaplasia and in gastric cancer patients. The specific activity of β-glucuronidase in gastric juice exceeded normal limits only in patients with atrophic gastritis and intestinal metaplasia or gastric cancer of the intestinal type. Increased alkaline phosphatase activity in intestinalized gastric mucosa was demonstrated cytochemically and biochemically. The results indicate that the presence and amount of intestinal specific enzymes in gastric juice may be of value in detecting lesions.

7761 COLONIC MOTILITY AND PRE-OPERATIVE BOWEL HABIT IN PATIENTS WITH DIARRHEA FOLLOWING VAGOTOMY AND PYLOROPLASTY. *(E.)* Waller, S. L. (Central Middlesex Hosp., London, England). *Proc. Int. Symp. Gastrointest. Motility, 4th, 1973.* pp. 197-199.

Following vagotomy and pyloroplasty 79 patients were carefully questioned about their pre- and postoperative bowel habit. Of 22 who complained of diarrhea after the operation, 8 had a pre-operative bowel habit suggestive of the irritable bowel syndrome. Of 57 patients who did not complain of diarrhea after the same operation, only 1 had apparent pre-operative irritable bowel syndrome. Postoperative diarrhea was of two distinct types, either early morning (13 patients) or post-cibal (9 patients). Left colonic studies before, during, and after eating were performed on 28 patients; 12 with early morning diarrhea, 8 with post-cibal diarrhea, and 8 without diarrhea. At sigmoidoscopy intense spasm was often noted in patients with early morning diarrhea (7 of the 12), but infrequently in either post-cibal (2 of 8) or control (2 of 8) patients. Left colonic motor activity was unremarkable in either post-cibal diarrhea or in controls. In patients with early morning diarrhea, colonic motor activity increased markedly during the 30 min after the meal. The onset of colonic response to food in these patients closely resembled that in patients with diarrhea due to the irritable bowel syndrome, except that this response occurred later in these postoperative patients. This delay in response may have resulted from initially slow gastric emptying for solids. It is suggested that pre-operative bowel habit may be important in deciding which patients are likely to develop diarrhea after vagotomy and pyloroplasty.

7762 METIAMIDE, AN H_2-RECEPTOR BLOCKER, AS INHIBITOR OF BASAL AND MEAL-STIMULATED GASTRIC ACID SECRETION IN PATIENTS WITH DUODENAL ULCER. *(E.)* Mainardi, M.; Maxwell, V.; Sturdevant, A. L.; Isenberg, J. I. (VA Wadsworth Hosp. Ctr., Los Angeles, Calif.). *N. Engl. J. Med.* 291(8):373-376, 1974.

The effect of p.o. metiamide on basal and peptone meal-stimulated gastric acid secretion was studied in 17 men (mean age 48 yr) with uncomplicated duodenal ulcer. Basal secretion after a single dose of metiamide (100, 200, or 300 mg) was investigated in 15 patients. Meal-stimulated secretion after 3 doses of metiamide (100, 200, and 300 mg) and placebo was studied in 5 patients. All 3 doses significantly inhibited basal and meal-stimulated acid secretion. Basal acid secretion decreased by 55% after 100 mg and by more than 80% after 200 or 300 mg. The differences were not statistically significant. Acid secretion stimulated by a 10% peptone meal at pH 5.5 decreased by more than 80% after 300 mg, and this inhibition was significantly higher than that after 100 or 200 mg. Inhibition of meal-stimulated secretion correlated significantly with peak blood metiamide level and 48-hr urinary excretion of the drug and its metabolites. Closer correlations were obtained with peak blood level than with ingested dose. Metiamide did not affect basal or peptone-stimulated blood gastrin levels. The patients reported no side effects and physical examinations and laboratory profiles revealed no abnormalities after drug administration. These findings indicate that metiamide may be useful in the treatment of patients with peptic ulcers. However, clinical testing of its prolonged use in the treatment of duodenal ulcer has been discontinued in the United States because transient agranulocytosis has occurred in 2 patients on chronic therapy.

7763 THE EFFECT OF VAGOTOMY AND DRAINAGE OPERATIONS ON THE RATE OF GASTRIC EMPTYING IN DUODENAL ULCER PATIENTS.

(E.) Davies, W. T.; Griffith, G. H.; Owen, G. M.; Shields, R. (United Cardiff, Velindre Hosp., Cardiff, Wales). *Br. J. Surg.* 61(7): 509-515, 1974.

To evaluate effects of vagotomy and 3 different types of gastric drainage procedures, the rate of gastric emptying was measured in 29 patients (5 women and 24 men, aged 29-71 yr) before and after duodenal ulcer surgery. The drainage procedures were the Finney or Heineke-Mikulicz pyloroplasty and gastrojejunostomy. Passage through the stomach of ^{51}Cr (200 μC), incorporated in a standard test meal, was followed by external scanning with an automatic scintiscanner. The rate of gastric emptying was expressed as the half-life (T 1/2) of the meal in the stomach. In all instances, postoperative rates were invalid due to temporary gastric stasis if measured before a 2-month recovery period. In 14 patients with Finney pyloroplasty, the mean T 1/2 was 59 min before surgery and 46.7 min afterwards. Nine patients with Heineke-Mikulicz pyloroplasty had a preoperative mean T 1/2 of 52 min which increased to 64.6 min postoperatively. Pre- and postoperative rates of gastric emptying followed no definite pattern in the 6 patients who had undergone gastroenterostomy. To check completeness of vagotomy, the insulin test was applied to 21 patients and 6 were found to be incompletely vagotomized: 4 with Finney drainage, 1 with Heineke-Mikulicz drainage, and 1 with gastroenterostomy. However, their postoperative T 1/2 did not differ significantly from the patients with complete vagotomy. These findings indicate that the Finney pyloroplasty is the most efficient drainage procedure of the 3 investigated in patients with duodenal ulcers. Although the long-term stability of the insulin test has recently been questioned, these results suggest that gastric emptying may be more related to the type of drainage operation used than to the vagotomy.

7764 PRODUCTION OF DUODENAL ULCERS IN THE RAT BY ADMINISTRATION OF DIGITOXIN.

(E.) Robert, A.; Nezamis, J. E.; Lancaster, C.; Badalamenti, J. N. (Exp. Biol., Upjohn Co., Kalamazoo, Mich.). *Experientia* 30(7):781-783, 1974.

The toxic and ulcerogenic effects of digitoxin (0.75 mg/kg for 4 days) were studied in 100 male and 100 female rats. Only 2% of the males died during digitoxin treatment compared with 18% of the females. The females also lost more weight than the males and 83% developed convulsions as opposed to 8% of the males. Duodenal ulcers were found in 50% of the females and in 2% of the males, while gastric ulcers occurred only in females (20%). Following 1 day of treatment, the stomach became progressively distended with food, being 3-5 times as large as that of control animals. In a separate experiment, animals were sacrificed 1-4 days after digitoxin treatment. The evolution of duodenal ulcers was apparent after 2 days with the appearance of tiny parallel red lines on the serosal surface, perpendicular to the duodenal axis and opposite to the mesenteric attachment; thrombosis could not be verified histologically. Incision revealed a small ulcer in the mucosa at the exact point where the red lines were evident on the serosa. With time, the red lines increased in number and covered an area of 2-3 mm; after 3-4 days, a well-formed ulcer was visible on the serosa as a bulging blister or a punched-out crater. The lesion reached the muscle layer in a few cases, but duodenal perforation occurred in only 1 animal. While the mechanism by which digitoxin induced duodenal ulcers is unknown, a vascular origin is suspected. Whether the greater resistance of male rats to digitoxin intoxication is due to androgens or other factors was not determined.

7765 PREVALENCE OF ALPHA$_1$-ANTITRYPSIN DEFICIENCY IN PATIENTS WITH GASTRIC OR DUODENAL ULCER.

(E.) Andre, F.; Andre, C.; Lambert, R.; Descos, F. (Edouard Herriot Hosp., Lyon, France). *Biomedicine (Paris)* 21(5):222-224, 1974.

In adult male patients (114 with duodenal ulcers, 83 with gastric ulcers, and 118 without gastrointestinal disease), serum α_1-antitrypsin concentrations were analyzed quantitatively by radial immunodiffusion. Deficiency levels were set at a serum value of less than 60% normal (1.68 mg/ml). Of the 315 patients, α_1-antitrypsin deficiency was observed in 24; all were of the heterozygous type because although the sera were not subjected to phenotyping, no values lower than 0.5 mg/ml (homozygous levels) were measured. The deficiency was found in 3.3% of control subjects, 9.6% of gastric ulcer patients, and 10.5% of duodenal ulcer patients. The last value was significantly greater than control deficiency levels. Comparison of the age of peptic ulcer onset in patients with and without α_1-antitrypsin deficiency showed no differences. According to the polygenic theory of inheritance for peptic ulcer, inheritance of the disease is separate for gastric and duodenal ulcers and higher for the latter. Blood group substances and secretor status, taste sensitivity, and salivary flow in response to citric acid stimulation have been reported to be highly correlated with duodenal ulcer. The present results suggest a similar significant correlation between α_1-antitrypsin deficiency and duodenal ulcer.

7766 THE EFFECT OF METOCLOPRAMIDE ON GASTRIC EMPTYING OF SOLID MEALS.

(E.) Hancock, B. D.; Bowen-Jones, E.; Dixon, R.; Dymock, I. W.; Cowley, D. J. (Univ. Hosp. South Manchester, Manchester, England). *Gut* 15(6):462-467, 1974.

Gastric emptying of a ^{51}Cr labeled (200 μC) solid meal was measured to gauge effects of metoclopramide in 10 normal controls and 10 duodenal ulcer patients following truncal vagotomy and pyloroplasty. One postvagotomy patient was examined 3 months after surgery, the remaining 9 at a mean interval of 15 days after surgery. Half the subjects received i.v. metoclopramide (10 mg/2 ml saline) while 2 ml saline was administered i.v. to the other 1/2 in a random double-blind manner. After a mean interval of 3-12 days, each subject received an i.v. injection of the other material. All were tested in a recumbent position, and gastric emptying was observed by a gamma camera for 90 min. Results in the 10 control subjects showed no significant differences between gastric emptying rates after metoclopramide or saline administration at any time, and the same pattern appeared in 4 postvagotomy patients with emptying times in the normal range expressed as half-life (T 1/2 30-150 min). In the other 6 vagotomy patients with abnormally delayed emptying times (mean T 1/2 369 min), metoclopramide produced a significant improvement (mean T 1/2 194 min). The results suggest that this drug accelerates emptying time only when the rate is delayed and not when it is normal. Although the mechanism by which metoclopramide exerts its effect is not yet clear, previous studies indicate that the stimulatory effect on gastric motility is not dependent on the integrity of the vagus nerves. In addition, the postoperative delay in gastric emptying does not appear to be related either to completeness of vagotomy or to size or type of pyloroplasty. Since impaired emptying can lead to epigastric fullness, discomfort, nausea, and vomiting, metoclopramide can relieve these symptoms by improved speed of emptying.

7767 THE INSULIN INFUSION TEST FOR VAGOTOMY.

(E.) Carter, D. C.; Pinto, D. J. (Dept. Surg., Makerere Univ., Kampala, Uganda). *East Afr. Med. J.* 51(2):206-213, 1974.

Studies were conducted to determine the reliability of a modified insulin infusion test in detecting intact vagal fibers in postvagotomy patients. In this test, 0.04 U of regular insulin/kg/hr are infused i.v. following a 12-hour fast, and gastric aspirates are periodically tested for acid concentration. In 9 normal volunteers, gastric acid secretion increased and reached a plateau within 75 min. Venous blood glucose levels fell to a mean of 28 mg% and remained at this concentration. A positive response to insulin infusion was also obtained in 3 preoperative duodenal ulcer patients and in 2 subjects with recurrent dyspepsia following unknown operations for duodenal ulcer. One patient was subsequently reexplored and found to have intact vagi. Two preoperative gastritis and gastric ulcer patients had unequivocally positive tests and a 3rd patient had an equivocally positive test. Only 4 of 14 postvagotomy peptic ulcer patients had a negative infusion test. The remaining 10, however, had recurrent symptoms and were thus suspect. The test thus appears relatively easy to use with no side effects and should be considered as an alternative to the potentially dangerous Hollander test.

7768 GASTROGRAFIN IN PERFORATED DUODENAL ULCER AND ACUTE PANCREATITIS.

(E.) Graser, G. M.; Fraser, I. D. (Leith Hosp., Edinburgh, Scotland). *Clin. Radiol.* 25(3):397-402, 1974.

Meglumine diatrizoate (50 ml, p.o.) was administered to 51 patients with suspected perforated duodenal ulcer or acute pancreatitis 5 min before chest and abdominal films were taken. By this method 24 of 25 cases (21 males and 4 females, aged 18-79 yr) with perforated duodenal ulcer were correctly diagnosed. Of these 25 cases, 17 (68%) showed free gas and 24 (96%) showed either free gas or a leak of meglumine diatrizoate or both. The one case not diagnosed had a sealed perforation. The time interval between the perforation and the x-ray examination seems to be an important factor in determining whether free intraperitoneal gas is seen. In all 7 patients in whom no free gas was noted but who had a leak of contrast medium a relatively short time elapsed (mean 2 1/2 hr) between perforation and examination, whereas the mean time interval for the whole series was 8 hr. By the use of meglumine diatrizoate 9 out of 10 cases of acute pancreatitis were also correctly diagnosed; all were males, aged 31-73 yr, and all were seen within 48 hr of onset of symptoms while the pancreas was still swollen and edematous. The 9 correctly diagnosed cases showed either stretching of the duodenal loop or upward displacement of the body of the stomach, or both these signs. This technique correctly diagnosed only 2 of 6 cases of active duodenal ulcer which had not perforated.

7769 EFFECT OF ATROPINE ON GASTRIN AND GASTRIC ACID RESPONSE TO PEPTONE MEAL.

(E.) Konturek, S. J.; Biernat, J.; Oleksy, J.; Rehfeld, J. F.; Stadil, F. (Med. Acad., Krakow, Poland). *J. Clin. Invest.* 54(3):593-597, 1974.

The action of atropine on meal- and pentagastrin-induced gastric acid secretion was studied in 6 patients with chronic duodenal ulcer disease (aged 37-53 yr). A test meal of 10% peptone solution adjusted to pH 5.0 was maintained in the stomach at a distention pressure of 15 cm H_2O. A modification of the intragastric titration method of Fordtran and Walsh was used to measure gastric acid output by monitoring the rate at which a solution of 0.5 M sodium bicarbonate had to be added to keep the pH of the gastric content consistant at the pH 5.0 value. Serum gastrin concentrations were measured simultaneously by radioimmunoassay. Pentagastrin infusion (2 μg/kg/hr for 13 15-min periods) caused acid output to peak at 10.0 mEq/15 min in the third 15 min period of infusion and then decline to about 83% of the initial peak at the end of the test. Atropine (25 μg/kg/hr i.v.) inhibited pentagastrin-induced acid secretion by about 30%. After atropine withdrawal, acid output returned towards control levels. Atropine inhibited meal-induced acid secretion by about 70%. After infusion of the test meal, the serum gastrin concentration rose to 3 times the fasting value. Atropine did not change serum gastrin levels. Thus atropine is a very strong inhibitor of food-induced gastric acid secretion but does not significantly change serum gastrin response to feeding in duodenal ulcer patients when postprandial gastric acidity and intragastric pressure are kept constant. All patients receiving atropine showed symptoms of dryness of mouth, increased pulse, dilation of pupils, and occasionally blurring of vision. The use of anticholinergic drugs clinically is not necessarily appropriate, since the toxic effects observed at this dose level probably could not be tolerated for more than an acute experimental procedure. Atropine inhibited meal-induced acid secretion more than pentagastrin-induced secretion, suggesting that cholinergic innervation may be important in the stimulation of the oxyntic glands by food.

7770 ELECTROMYOGRAPHIC STUDY OF MODIFICATIONS OF GASTRODUODENAL MOTILITY AFTER PROXIMAL SELECTIVE VAGOTOMY IN MAN. *(E.)* Salducci, J.; Picaud, R.; Naudy, B.; Dalmas, H.; Monges, H. (Nord Hosp., Marseille, France). *Digestion* 10(3):242, 1974.

Proximal selective vagotomy was performed on 10 patients with duodenal ulcer. An electromyographic study of gastroduodenal motility was subsequently performed. Readings started 24 hr after operation and continued for 7 days. Slow wave or basic electrical rhythm was recorded as triphasic or polyphasic complexes, and spiking activity was recorded as bursts of fast spike potentials. On the 1st day, gastric basic electrical rhythm occurred regularly and migrated abroad with a fixed rhythm. However, within 3 days after operation, a transitory increase of the basic electrical rhythm frequency and a slowing of the basic electrical rhythm conduction was noted. These modifications then disappeared. Spiking activity was recorded in the duodenum 24 hr after operation and appeared in the stomach 48 hr postoperatively. Such activity was viewed as bursts of fast spikes superimposed on each gastric and duodenal basic electrical rhythm. Recordings obtained 48 hr postoperatively were similar to those performed on cholecystectomized patients. This electromyographic study supports clinical evidence that important disturbances of gastric emptying do not occur following selective vagotomy and suggests that a drainage procedure may be unnecessary.

7771 MECHANISM OF ULCEROGENIC ACTIVITY OF RESERPINE IN ALBINO RATS. *(E.)* Gupta, M. B.; Tangri, K. K.; Bhargava, K. P. (King George's Med. Coll., Lucknow, India). *Eur. J. Pharmacol.* 27(2): 269-271, 1974.

Reserpine (5 mg/kg, i.m.) was injected into 10 adult albino rats. The stomach and duodenum were examined 20 hr after injection. To elucidate the mechanism of ulcerogenic activity of reserpine, the animals were pretreated i.p. 30 min prior to reserpine injection with drugs known to influence adrenergic and cholinergic functions, except for 6-hydroxydopamine which was administered 24 hr earlier. In some experiments, reserpine-induced gastric ulceration was investigated in bilaterally adrenalectomized animals and after lateral cerebral ventricle injection. I.m. reserpine (5 mg/kg) showed 100% ulcerogenic activity, but lateral cerebral ventricle injection (250 μg/kg) failed to cause gastric ulceration. Tetrabenazine (200 mg/kg, i.p.) also failed to induce gastric ulceration in albino rats. Bilateral adrenalectomy did not protect the animals against gastric ulceration induced by peripheral administration of reserpine. The α-adrenoceptor antagonists phenoxybenzamine and phentolamine (each 5 mg/kg) significantly reduced the ulcerogenic activity of reserpine, whereas the β-adrenoceptor antagonist propranolol (5 mg/kg) did not protect animals against reserpine-induced gastric ulceration. Ulcerogenic activity was not attributed to 6-hydroxydopamine (50 mg/kg) but the drug did afford protection against the ulcerogenic activity of reserpine. The cholinolytic agent atropine methylnitrate (5 mg/kg also significantly protected against reserpine-induced gastric ulceration. It is suggested that catecholamines released from peripheral sympathetic nervous system are involved in the production of gastric ulcers by reserpine. The protective effects of both 6-hydroxydopamine and atropine methylnitrate indicate the involvement of peripheral cholinergic and adrenergic mechanisms in the ulceration induced by reserpine. However, it is not known how far the cholinergic mechanism is concerned in the release of the adrenergic transmitter necessary for the production of ulcer by reserpine.

7772 ENDOSCOPICAL AND HISTOLOGICAL STUDIES ON VITAL STAINING OF DUODENAL MUCOSA. *(E.)* Kohli, Y.; Nakajima, M.; Kawai, K. (Kyoto Prefect. Univ. Med., Japan). *Endoscopy* 6(2):105-110, 1974.

In endoscopic examinations of 103 patients, 0.2% methylene blue solution or 0.2% indigocarmine solution was directly scattered on the duodenal mucosa through a Teflon tube inserted in the duodenofiberscope. The patients had duodenal ulcer or its scar (49 cases), duodenal erosion (5), duodenal polyp (4), gastroduodenal ulcer or its scar (13), gastric ulcer or its scar (19), gastric polyp (2), and gastritis (11). Both dyes were scattered on separate occasions in 34.9% of the cases, while the methylene blue solution was used in 26.2% of cases and the indigocarmine solution in 38.9%. With the indigocarmine solution, minute elevations were observed in detail in 17 of 58 cases unrecognized at usual endoscopy; similarly, 30 cases of minute depression were observed among 67 cases negative at usual endoscopy. Duodenal villi in normal mucosa were stained by the methylene blue solution whereas villi around duodenal ulcer remained unstained and appeared irregular in shape. Comparison with histological findings showed that the stainability of duodenal mucosa corresponded to the healing of duodenal ulcer or the degree of glandular maturity of the duodenal mucosa. Mucosal staining by the 0.2% methylene blue solution indicates complete healing of duodenal ulcer or duodenitis.

7773 A DUODENAL ROLE IN GASTRIN RELEASE. *(E.)*

Hayes, J. R.; Ardill, J.; Kennedy, T. L.; Buchanan, K. D. (Dept. Med., Queen's Univ. Belfast, Northern Ireland). *Gut* 15(8):626-629, 1974.

Plasma gastrin response to a protein test meal was determined in 5 patients with the dumping syndrome following selective vagotomy and pyloroplasty, in 5 patients with pyloric stenosis, and in 10 duodenal ulcer patients asymptomatic after selective vagotomy and pyloroplasty or selective vagotomy and gastrojejunostomy. In patients without pyloric obstruction, the peak gastrin response to protein occurred at 30-45 min. In patients with the dumping syndrome and presumed rapid gastric emptying, peak levels occurred in the 15-min sample, suggesting that food must pass into the duodenum for gastrin levels to rise. In contrast to patients with uncomplicated duodenal ulceration and patients with the dumping syndrome, test gastrin levels in patients with pyloric stenosis did not differ significantly from the fasting level. In 1 patient, however, the gastrin response to protein feeding peaked at 60 min, further strengthening the concept of a duodenal role in the mechanism of gastrin release. Comparison of the gastrin responses in patients with pyloroplasty and in patients with gastrojejunostomy showed that gastrin response was significantly greater when protein entered the duodenum directly than when it was possible for food to bypass the duodenum. Further evidence of a duodenal role in gastrin release was the finding in 1 normal subject that gastrin levels peaked 15 min after intraduodenal administration of the test meal, whereas with intragastric administration peak levels occurred at 30 min.

7774 ACID AND PEPSIN SECRETION IN DUODENAL ULCER PATIENTS IN RESPONSE TO GRADED DOSES OF PENTAGASTRIN OR PENTAGASTRIN AND CARBACHOLINE BEFORE AND AFTER PROXIMAL GASTRIC VAGOTOMY. *(E.)*

Roland, M.; Berstad, A.; Liavag, I. (Aker Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(6):511-518, 1974.

Before and 3 and 6 months after proximal gastric vagotomy, 9 patients with duodenal ulcer (2 women and 7 men, aged 19-65 yr) were infused with graded doses of pentagastrin (0.15, 1.5, or 15 μg/kg/hr) on separate days and in random order. At 6 months carbacholine (1-2 μg/kg/hr) was infused simultaneously with pentagastrin. The calculated maximal acid output in response to pentagastrin alone decreased from 34.7 mEq/hr preoperatively to 17.3 mEq/hr 3 months after the operation, and the half maximal response increased from 0.05 to 0.18 μg/kg/hr. When carbacholine was added to pentagastrin, maximal acid output was 18.4 mEq/hr and the half maximal response was reduced to 0.07 μg/kg/hr. Proximal gastric vagotomy caused a greater reduction of acid output stimulated with a low than with a high dose of pentagastrin. Because of the preoperative fall in pepsin output with the highest dose of pentagastrin, maximal and half maximal responses could not be calculated. After vagotomy the maximal response for pepsin with pentagastrin alone was 98.9 mg/hr. With carbacholine added to pentagastrin, the maximal pepsin response increased to 132.0 mg/hr. The dose of pentagastrin giving half maximal response for pepsin was 0.07 μg/hr postoperatively and remained almost unchanged (0.05 μg/kg/hr) when carbacholine was added. The results indicate that proximal gastric vagotomy decreases the sensitivity of the parietal and chief cells to pentagastrin stimulation. Carbacholine restores the sensitivity of the parietal cells to preoperative levels without influencing maximal acid secretory capacity. Although carbacholine does not change the postoperative sensitivity of the chief cells, it significantly influences maximal pepsin secretion.

7775 TAUROCHOLATE METABOLISM AFTER TRUNCAL VAGOTOMY AND PYLOROPLASTY OR ANTRAL RESECTION.

(E.) Arnesjo, R.; Stahl, E. (Dept. Surg., Univ. Lund, Sweden). *Scand. J. Gastroenterol.* 9(6):601-606, 1974.

Tracer doses of doubly labeled taurocholate (^{25}S-tauro-7-^{3}H-cholate) corresponding to 10 μC of each isotope were given in a test meal to 8 patients (2 women and 7 men, aged 29-55 yr) who had undergone truncal vagotomy and pyloroplasty or antral resection for benign duodenal ulcer. Duodenal aspirates from the subsequent 7 days were examined. Results were compared with those obtained from 9 healthy controls (4 women and 5 men, aged 22-38 yr). Mean taurocholate pool size was 0.59 ± 0.18 g in the 8 patients and 0.90 ± 0.30 g in controls; the half-life of the taurocholate pool was 1.2 ± 0.5 days in patients and 2.1 ± 0.5 days in controls. These differences were statistically significant. The mean daily production of taurocholate in patients was 0.29 ± 0.05 g and was not significantly different from that of the control group (0.32 ± 0.14 g). Both the average fractional deconjugation rate and the 7-α-dehydroxylation rate were significantly increased in patients (0.19 ± 0.06 and 140 ± 2.5%/day, resp.) compared with controls (0.10 ± 0.06 and 5.8 ± 2.4%/day). The alteration in taurocholate metabolism suggests that contamination of the small intestine with colonic bacteria plays a role in the genesis of the altered bowel habits subsequent to truncal vagotomy and possibly also of postvagotomy diarrhea.

7776 THE FEATURES AND COURSE OF BILE VOMITING FOLLOWING GASTRIC SURGERY. *(E.)*

Griffiths, J. M. T. (Western Gen. Hosp., Edinburgh, Scotland). *Br. J. Surg.* 61(8):617-622, 1974.

Of 1311 patients (973 men and 338 women) undergoing peptic ulcer surgery over an 11-yr period, 119 (9.1%) developed postoperative bile vomiting. The incidence of vomiting was less than 1% up to age 20, 3-8% between 30-50 yr, and 20% when surgery was performed on patients over 60 yr. Both men and women were equally at risk. The overall incidence of bile vomiting was highest after vagotomy and gastrectomy (15.7%) and vagotomy and gastrojejunostomy (10.7%). The complication did not occur after 55 simple gastrojejunostomies. Vomiting developed within 1 month of surgery in 39% of the patients, and 57% suffered a significant degree of disability for 6-14 yr after onset. The principal organic cause of the vomiting appeared to be gastric outlet obstruction and gastritis due to bile reflux. Of the 26 patients who required reoperation, 8 had normal findings on barium examination, but at operation definite pathology (e.g., gastritis, stomal ulcer, obstruction of the efferent loop) was discovered in each case. Of 39 patients referred for formal psychiatric assessment, 17 had an endogenous or reactive depression; no abnormality was found in the other 22 cases. Of the 85 patients managed conservatively, vomiting has settled completely in 19.8%, 47.7% have occasional vomiting, and 9.1% are still disabled. An organic basis should be suspected if vomiting persists longer than 6 months after peptic ulcer surgery. Investigations should include barium studies and endoscopy. A role for psychological symptoms in the etiology should be viewed with caution. Negative investigation does not necessarily contraindicate reoperation, especially when symptoms are disabling.

7777 INFLUENCE OF TRUNCAL VAGOTOMY ON CANINE GASTRIC EMPTYING OF LIQUIDS.

(E.) Springfield, A. C.; Weddle, II, C. O.; Ormsbee, III, H. S.; Barreras, R. F.; Bass, P. (Dept. Surg., Univ. Wisconsin, Madison). *Am. J. Surg.* 128(5):678-682, 1974.

The effect of truncal vagotomy and truncal vagotomy with pyloroplasty on canine gastric emptying was studied with a liquid test meal (300 ml trisodium citrate, 19.6 g/liter) and a liquid-fat meal (300 ml trisodium citrate with 10 mM oleic acid). The time required for the total gastric contents to be reduced to 150 ml was 12 min for the citrate meal and 54 min for the citrate-fat meal. The emptying rate was not significantly altered by truncal vagotomy alone or truncal vagotomy combined with pyloroplasty. Bethanechol (0.1 mg/kg s.c.) and insulin (0.5 U/kg i.v.) enhanced the presurgery emptying of the citrate-fat test meal by 26.9 and 62.1%, resp. Bethanechol significantly increased gastric emptying in animals with truncal vagotomy (26.9-71.1%) and truncal vagotomy with pyloroplasty (26.9-80.1%). In contrast, the enhanced emptying with insulin was significantly reduced after truncal vagotomy alone (62.1-17.5%) or truncal vagotomy combined with pyloroplasty (62.1-22.8%). Fasting gastrin levels were increased after truncal vagotomy (100.4 *versus* 137.5 pg/ml) and were significantly reduced after the addition of pyloroplasty (137.5 *versus* 71.9 pg/ml). The results suggest that the intact vagus nerve is important in the gastric emptying of solids but not in the gastric emptying of liquids. The effects of bethanechol and insulin demonstrate the importance of parasympathetic nerves in controlling stomach emptying.

7778 ROLE OF GASTRIC IRRADIATION IN MANAGEMENT OF PEPTIC ULCERATION AND OESOPHAGITIS.

(E.) Findlay, J. M.; Newaishy, G. A.; Sircus, W.; McManus, J. P. A. (Western Gen. Hosp., Edinburgh, Scotland). *Br. Med. J.* 3(5974):769-771, 1974.

A group of 24 at-risk patients with peptic esophagitis or ulcerations of the stomach or duodenum were treated with gastric radiotherapy. Surgery was precluded because of failure of previous surgery, associated medical complications, or age (83% of the patients were aged 60 yr or older). Presenting symptoms were dysphagia (11 cases), heartburn (8), epigastric pain (8), bleeding (7), and backache (1). Of the 24 patients, 16 had complete symptomatic relief after a single course of therapy (1500 r given as two 5-day courses of 150 r/day). Three patients had partial symptomatic relief and another 3 achieved complete symptomatic relief after further courses of irradiation in increased dosage. Symptomatic improvement was closely correlated with endoscopic appearance in all but 1 case; the exception was a patient with severe esophagitis who obtained complete symptomatic relief without endoscopic change. Mean acid output was reduced to 30% of preirradiation levels at 10.7 months and to 58% at 30 months. No morbidity was observed attributable to the irradiation.

7779 THE RESPONSE OF GASTRIC SECRETION AND SERUM GASTRIN TO AN INSULIN INFUSION TEST IN PATIENTS WITH DUODENAL ULCER.

(E.) Girvan, D. P.; Hansky, J.; Spencer, J.; Baron, J. H. (Roy. Postgrad. Med. Sch., London, England). *Am. J. Dig. Dis.* 19(11):977-986, 1974.

An i.v. infusion of insulin (014 U/kg/hr for 2 1/2 hr) was performed on 26 patients with chronic duodenal ulcer. In 15 patients this infusion test was compared with the standard test of a single i.v. injection of insulin (0.2 U/kg). The mean lowest blood glucose level in the infusion group (25.1 mg/100 ml) was significantly higher than in the standard test (17.4 mg/100 ml), and the interval from injection to acid stimulation was almost twice as long (75 *versus* 45 min). The peak acid output and mean rise in acidity were comparable in the 2 procedures. Serum gastrin responded reciprocally to insulin-induced hypoglycemia with a significant inverse correlation between blood glucose and gastrin. In 13 patients tested after vagotomy, there was no significant difference in the rise of acidities in the insulin infusion and the standard insulin test groups, and the Hollander status was the same in all but 1 patient. The mean basal, peak, and absolute rise of serum gastrin in unoperated patients and patients with incomplete vagotomy (9) were almost identical. In patients with complete vagotomy (6), there was no significant rise in serum gastrin after insulin infusion. Side effects were fewer and less severe in patients undergoing the infusion test than in the standard test. Tremor and chest discomfort, both signs of more severe hypoglycemic response, were mentioned on 2 occasions in the standard test group but never in the infusion group. The insulin infusion test is recommended as a safer and more acceptable test since it avoids severe hypoglycemia and has milder side effects while achieving comparable acidity and acid outputs. Serum gastrin measurements after either test provide no additional help in assessing the completeness of vagotomy.

7780 EFFECT OF HISTAMINE H_2-RECEPTOR BLOCKADE ON VAGALLY INDUCED GASTRIC SECRETION IN MAN.

(E.) Carter, D. C.; Forrest, J. A. H.; Werner, M.; Heading, R. C.; Park, J.; Shearman, D. J. C. (Roy. Infirm., Edinburgh, Scotland). *Br. Med. J.* 3(5930):554-556, 1974.

Metiamide, an antagonist of histamine H_2 receptors, was administered i.v. to normal subjects and to patients during vagal stimulation with a constant infusion of insulin. The 6 normal subjects (aged 27-34 yr) received 0.03 U/kg/hr insulin for 150 min. After 60 min of insulin infusion, 250 mg metiamide diluted to 13.2 ml was delivered at a constant rate of 200 mg/hr for 75 min. Five male patients with chronic peptic ulceration (4 duodenal and 1 gastric, aged 34-63 yr) received identical treatment except that an insulin dose level of 0.04 U/kg/hr was used. An additional 4 patients (3 men and 1 woman, aged 34-52 yr) with chronic duodenal ulceration received 0.04 U/kg/hr insulin for 180 min. After 105 min, an i.v. infusion of 200 mg metiamide diluted to 10.6 ml was carried out at a constant rate for 75 min. An additional 5 subjects (2 healthy volunteers and 3 with peptic ulcer disease) were treated with tritium-labeled metiamide to estimate the plasma metiamide levels achieved. In normal and peptic ulcer subjects there were reductions of 70% and 71%, resp., in gastric acid output compared with control tests on the same subjects. The decreased acid output resulted from a reduction in both volume of secretion and acid concentration. The plasma concentrations achieved were comparable to those following a 300 mg p.o. dose of this metiamide. The drug is thus a potent inhibitor of vagally-induced gastric acid secretion.

7781 THE EFFECT OF VAGOTOMY ON THE INHIBITION OF GASTRIC SECRETION BY INTRADUODENAL ACID.

(E.) Ward, A. S. (Roy. Infirm., Sheffield, England). *Br. J. Surg.* 61(9):698-704, 1974.

The effect of intraduodenal hydrochloric acid on pentagastrin-stimulated gastric secretion was studied in 17 control subjects (14 men and 3 women), 32 preoperative duodenal ulcer patients (31 men and 1 woman, average age 45 yr), and 28 vagotomized patients (24 men and 4 women, average age 47 yr). Of the vagotomized patients, 16 underwent truncal vagotomy and pyloroplasty, 6 selective vagotomy and pyloroplasty and 6 highly selective vagotomy. Inhibition of acid output occurred in 15 of 17 controls. The response was immediate and lasted for over 30 min in nearly all cases. The mean acid output for the group as a whole fell from 5.65 to 3.15 mEq/10 min. The mean inhibition for the group was 2.68 mEq/10 min. Inhibition occurred in 22 of the 32 preoperative duodenal ulcer patients. The mean plateau output for this group fell from 7.65 to 5.39 mEq/10 min. Significantly, the mean inhibition was 2.26 mEq/10 min. There was no response to intraduodenal acid in any patient tested after selective and highly selective vagotomy. This study indicates that acid in the duodenum inhibits pentagastrin-stimulated gastric secretion in man. This inhibition is not related to changes in pyloric loss. The results suggest that gastric secretory inhibition by intraduodenal acid is a vagal phenomenon in man. Selective and highly selective vagotomy do not carry any particular advantage over truncal section in terms of preserving this response.

7782 THE EFFECT OF CALCIUM ON GASTRIC ACID AND GASTRIN SECRETION IN ANTRECTOMIZED SUBJECTS.

(E.) Christiansen, J.; Rehfeld, J. F.; Stadil, F. (Bispebjerg Hosp., Copenhagen, Denmark). *Gut* 15(8):622-625, 1974.

Serum gastrin concentrations and gastric acid secretion were measured during infusion of saline and calcium gluconate in 9 patients (8 men and 1 woman, aged 22-60 yr) who had undergone antrectomy for duodenal or prepyloric ulcer at least 3 months prior to examination. Five of the patients had a gastroduodenostomy (Billroth I) and 4 had a gastrojejunostomy (Billroth II). Saline was administered by constant i.v. infusion (flow 30 ml/hr) for a control period of 2 hr. Calcium gluconate was infused over the next 2 hr with a flow of 30 ml/hr, delivering 4 mg Ca^{++}/kg/hr. Serum calcium concentrations rose significantly during calcium infusion from 9.8 ± 0.1 to 12.0 ± 0.4 mg/100 ml. The mean basal serum gastrin concentration rose during calcium infusion from 48 ± 4 to 55 ± 6 pgEq/ml. However, analysis of the data of individual subjects showed that this rise could be ascribed to a rise in a single patient. The volume of secretion was unchanged. Acidity decreased slightly during calcium infusion. Acid output also decreased slightly during saline and calcium infusion. Secretory responses during saline and calcium infusion were not influenced by duodenal reflux, as no significant differences in the osmolarity of the gastric juice were noted. Results of this study indicate that the release of antral gastrin is a prerequisite of calcium to stimulate gastric acid secretion in man. However, this does not exclude other effects of calcium on the gastric secretory system.

7783 SERUM GASTRIN AND GASTRIC ACID RESPONSES TO MEALS AT VARIOUS pH LEVELS IN MAN.

(E.) Konturek, S. J.; Biernat, J.; Oleksy, J. (Med. Acad., Krakow, Poland). *Gut* 15(7):526-530, 1974.

Serum gastrin and gastric acid responses to a test meal of 10% peptone were measured in 6 duodenal ulcer patients (aged 20-24 yr) using intragastric titration at pH levels ranging from 5.5 to 1.0. In this way the pH profile for inhibition of serum gastrin release and gastric acid secretion was established. A peptone meal adjusted to pH 5.5 produced an abrupt rise in gastric acid secretion similar to the maximal response to histamine. A graded decrease of pH of the peptone meal to 1.0 resulted in the progressive inhibition of gastric acid secretion and a concomitant suppression of the serum gastrin level. Exogenous secretin given in graded doses ranging from 0.25 to 2.0 U/kg/hr caused a dose-related inhibition of gastric acid secretion and the suppression of serum gastrin level. A significant inhibition of acid secretion occurred at the dose of 0.5 U/kg/hr and inhibition reached about 90% at the dose of 2.0 U/kg/hr. The serum gastrin level decreased to about 50% of control at the dose of 2.0 U/kg/hr. Thus, gastric acid secretion and the rise in serum gastrin levels in response to an experimental meal are less when the gastric contents become more acidic. The pH changes of the gastric content evoked in this study may occur under natural conditions and it is reasonable to expect that in duodenal ulcer patients the gastric inhibitory mechanisms are activated during normal digestion of food. The decrease of gastric acid response to a peptone meal at a low pH was probably due to the suppression of gastrin release and direct inhibition of parietal cells by a low pH.

7784 FAECAL FAT EXCRETION AFTER TRUNCAL, SELECTIVE, AND HIGHLY SELECTIVE VAGOTOMY FOR DUODENAL ULCER. *(E.)* Edwards, J. P.; Lyndon, P. J.; Smith, R. B.; Johnston, D. (Gen. Infirm., Leeds, England). *Gut* 15(7):521-525, 1974.

Fecal fat excretion was measured on a metabolic ward in 16 patients with duodenal ulcer before operation, and in patients who were in good health after truncal vagotomy and pyloroplasty (11 patients), bilateral selective vagotomy and pyloroplasty (9), or highly selective vagotomy without a drainage procedure (12). Excretion of fecal fat was significantly greater in patients after both truncal vagotomy (6.4 g/day) and selective vagotomy with drainage (4.9 g/day) than in patients before operation (3.1 g/day). Fat excretion in highly selective vagotomy patients (3.6 g/day) was little different from that of preoperative patients. The mean interval between operation and the measurement of fecal fat excretion was 30 months in patients with highly selective vagotomy, 44 months after truncal vagotomy plus pyloroplasty, and 67 months after selective vagotomy plus pyloroplasty, but there was no evidence that fecal fat output correlated with the length of time after operation. If steatorrhea is defined as a fecal fat output of more than 6 g/day, 1 of 16 preoperative patients with duodenal ulcer (6%) had steatorrhea, as well as 1 of 12 highly selective vagotomy patients (8%), 1 of 9 patients after selective vagotomy and pyloroplasty (11%) and 5 of 11 patients after truncal vagotomy and pyloroplasty (45%). The results show that preservation of the extragastric vagal fibers is not of crucial importance for the digestion of fat. The main reasons for the increased loss of fecal fat after both truncal vagotomy and selective vagotomy with a drainage procedure are impairment of the milling function of the antrum, and unregulated gastric emptying through the pyloroplasty or gastroenterostomy. Since the amount of fat in the feces is a nonspecific index of malabsorption, the day-to-day losses of protein, minerals, and vitamins in the feces may be less after highly selective vagotomy than after vagotomy with drainage.

7785 A COMPARISON OF GASTRIC EMPTYING BEFORE AND AFTER VAGOTOMY WITH ANTRECTOMY AND VAGOTOMY WITH PYLOROPLASTY. *(E.)* Donovan, I. A.; Gunn, I. F.; Brown, A.; Alexander-Williams, J.; Clark, R. J. (Gen. Hosp., Birmingham, England). *Surgery* 76(5): 729-732, 1974.

The rate of gastric emptying of a 750 ml solution of 10% dextrose in water was studied by a double-dye dilution technique in 23 patients with duodenal ulcer. Nine of these patients were restudied 3 months after vagotomy with antrectomy and 14 were restudied 3 months after vagotomy with pyloroplasty. The volume emptied 10 min after ingestion of the dextrose meal was used as a measurement of initial gastric incontinence or cascading; the time taken for complete emptying of the stomach was thought to represent active muscular gastric emptying. Statistical comparison of preoperative and postoperative results by Student's t test showed that both operations significantly shortened the time for complete emptying of the stomach. However, a significant increase above preoperative levels in the volume of early emptying occurred only after vagotomy with pyloroplasty. After vagotomy with antrectomy, 5 of the 9 patients emptied rapidly, whereas 4 behaved similarly to the way they did before surgery. Rapid early emptying of the meal after either operation correlated with the clinical symptoms of dumping.

7786 PERIPHERAL AND GASTRIC FIBRINOLYSIS IN PEPTIC ULCER PATIENTS. *(E.)* Prokopowicz, J.; Gabryelewicz, A.; Wolosowicz, N.; Puchalski, Z.; Tolloczko, A. (Inst. Med., Bialystok, Poland). *Haematologia (Budap.)* 7(3-4):381-384, 1973.

The plasma fibrinolytic system in 9 gastric, 9 duodenal ulcer patients, and 9 control patients with cholelithiasis without any evident liver lesion was studied using blood collected from peripheral and gastric blood vessels during surgery for cholelithiasis. Euglobulin lysis time was significantly shortened in gastric venous blood but normal in peripheral venous blood. The plasma fibrinogen level was lower in gastric venous blood than in peripheral blood. The activity of both antiplasmins in gastric venous blood was lower than in healthy control subjects. Plasminogen activity was almost the same in both peripheral and gastric venous blood in gastric ulcer patients. Antithrombin activity in patients and controls alike was higher in gastric than in peripheral venous blood, but was highest in ulcer patients. Antithrombin VI activity was higher in peripheral blood in ulcer patients than in controls. These results suggest a possible pathogenic role of fibrinolytic activity in peptic ulcer. Stress, important in peptic ulceration, activates the fibrinolytic system. The activation of gastric fibrinolysis may induce hemorrhage and aid peptic ulcer development. The decrease of the plasma fibrinogen level in gastric venous blood in ulcer patients may result from high euglobulin fibrinolytic activity, which correlates well with the increased antithrombin VI activity. These data indicate that the lower plasma fibrinogen level is due to the moderate increase of euglobulin fibrinolytic activity and not the reverse. The higher concentration of antithrombin VI, the degradation products of fibrinogen and fibrin, in the gastric vein of ulcer patients may disturb platelet aggregation and cause local hemorrhaging. The use of antifibrinolytic therapy is recommended when gastric hemorrhage is complicating peptic ulcer.

7787 PEPTIC ULCER DISEASE: A CLINICAL STUDY IN 73 CHILDREN. *(E.)* Deckelbaum, R. J.; Roy, C. C.; Lussier-Lazaroff, J.; Morin, C. L. (Montreal Children's Hosp., Canada). *Can. Med. Assoc. J.* 111(3):225-228, 1974.

A review was made of 73 children with primary or secondary peptic ulcer disease. Ulcers in patients in whom an underlying disease, a drug, or a toxic substance causally related to peptic ulcer disease could be identified were labeled secondary. Secondary ulcers predominated in the younger age group (1 month to 6 yr). The primary ulcer group comprised 39 duodenal and 9 gastric ulcer patients. Vomiting was prominent in younger patients while pain and bleeding were more common in older children (6-18 yr). A positive family history was obtained in 11 children with primary duodenal ulcers, but in none with gastric ulcers. Primary ulcers were exclusively gastric in the younger age group, duodenal in older children. Most duodenal ulcers (39/53) were primary; most gastric ulcers (12/21), secondary. Primary gastric ulcers occurred in the antrum (5 cases), or pylorus (4). Of the secondary gastric ulcers, 7 were antral, 3 pyloric, and 2 in the body of the stomach. Most duodenal ulcers involved the bulb, but 2 were postbulbar and 1 was in the 3rd part of the duodenum. Bleeding and/or perforation was the common mode of presentation in secondary ulcers. Medical treatment consisting of blood replacement, nasogastric drainage, iced saline lavage, antacids, anticholinergic agents, and diet was used in 53 patients. Surgery was required in 12 primary and 6 secondary cases. Emergency surgery was performed for 6 perforated secondary ulcers and 2 primary ulcers. Follow-up data on 49 patients (34 primary and 15 secondary) showed that 8 children with secondary ulcers died, 5 from the underlying disease and 3 as a direct result of the ulcer. Of the primary ulcer follow-up studies, only 1 of 4 children diagnosed at less than 6 yr of age had recurrent symptoms. However, 19 of 30 older patients suffered recurrence with gastrointestinal bleeding or pain. All 12 primary ulcer patients who were operated on had a straightforward recovery and have remained well. Peptic ulcer diagnosis in children should be considered not only when there is an aggregation of suggestive symptoms, but also under the following conditions: chronic abdominal pain at night or in early morning hours; recurrent vomiting related to eating; anemia, if occult blood occurs in the stools; vague gastrointestinal complaints in a patient with positive family history for duodenal ulcer; and disease associated with stress if the central nervous system is involved or if corticosteroids have been given.

7788 BONE MINERAL AFTER PARTIAL GASTRECTOMY I. *(E.)* Alhava, E. M.; Aukee, S.; Karjalainen, P. (Univ. Centr. Hosp., Kuopio, Finland). *Scand. J. Gastroenterol.* 9(5):463-466, 1974.

The bone mineral density (g/cm^3) of partial gastrectomy patients (55 men and 15 women) was determined 3.3-8.5 yr after surgery and compared with that of coeval persons with healthy bones. In addition, the bone mineral metabolism of these operated patients was studied by comparing the mean pre- and postoperative serum calcium, phosphorus, alkaline phosphatase, and total protein values. The operations consisted of antrectomy, gastroduodenostomy (Billroth I anastomosis) in addition to selective vagotomy. The bone mineral densities of female patients were significantly lower than the corresponding normal values. Women also displayed a statistically significant correlation between the decrease in mineral density and the interval between surgery and the time of measuring. The mineral density of men also declined, but not significantly so. The serum calcium level declined postoperatively, perhaps due to malnutrition, maldigestion, and malabsorption. The serum phosphorus, alkaline phosphatase, and protein levels rose. As the serum protein level rose, the decrease in the calcium content was real. The postoperative increase in the phosphorus level is accounted for by the drop in the calcium level. The changes in the serum calcium and phosphorus levels established in this study gave no indication of the osteomalacia syndrome in which the serum calcium drops and the phosphorus level declines or remains unchanged. The difference between the mineral densities of subjects with healthy bones and patients operated on for ulcer, and possibly the change in the serum calcium, phosphorus and alkaline phosphatase values, may be regarded as signs of post-gastrectomy bone disease.

SMALL INTESTINE

809 WHY ARE SMALL BOWEL TUMORS RARE? AN EXPERIMENTAL MODEL. *(E.)* Calman, K. C. Western Infirm., Glasgow, Scotland). *Gut* 15(7): 52-554, 1974.

transplantable tumor (Gardner lymphosarcoma) was inected either into the submucosa of the stomach or small ntestine (5-6 cm from the ileo-cecal region) of CBA ice, and the incidence of subsequent tumor growth was tudied under conditions which altered the immune status of the host mouse. Normal mice, mice deprived by thymectomy and irradiation (T-cell-deficient mice), and reconstituted mice (prepared as the deprived animals but given a thymus graft) were used. Tumors developed in 65% of normal mice injected in the stomach, whereas tumors developed in 34% of mice injected in the small intestine. Reconstituted animals also showed a significant increase in the number of tumors developing in the stomach compared with those developing in the small intestine. There was even a higher incidence of stomach tumors (92%) in reconstituted animals as compared with controls. In deprived mice the incidence of tumors was the same at each site. It is stressed that the reconstituted animals had received the same dosage of radiation (800 r) as had the deprived animals, yet the presence of a functioning thymus graft restoring the T cell pool resulted in a significant decrease in tumor take in the small intestine. Thus, radiation itself did not alter locally the capacity of the gut to accept tumor challenge. This suggests that local immune responses can suppress the development of tumors of the small intestine. In conditions such as Crohn's disease or celiac disease, a prospective study of the immunological status of the small intestine may indicate which patients are likely to develop subsequent neoplastic change.

7810 SMALL INTESTINAL DISEASE IN T CELL DEFICIENCY. *(E.)* Horowitz, S.; Lorenzsonn, V. W.; Olsen, W. A.; Albrecht, R.; Hong, R. (Univ. Wisconsin Med. Ctr., Madison). *J. Pediatr.* 85(4): 457-462, 1974.

Intestinal lesions are reported in 4 children (3 boys and 1 girl, aged 4 months to 5 yr) with impaired cell-mediated immunity. One child had an isolated T cell defect and 3 had significant B and T cell defects. All 4 patients had a long history of diarrhea and evidence of malabsorption. Giardiasis was not the cause of their diseases. Microscope examination of biopsy material from the proximal small bowel showed the presence of large "foamy" macrophages of the lamina propria. These were most prominent at the tip of the villus with a progressive decrease in their size and their content of vacuoles, lysosomes, and pleomorphic inclusions in more proximal areas of villi. Absorptive cells, except for a small area at the base of the villus, were abnormal. The macrophages varied in size between 100 and 200 μ. It is likely that mucosal structural alterations in these patients accounted in large part for the gastrointestinal symptoms, for the absorptive surface area was reduced with a decreased height of villi and a reduction in the length of the microvilli. Although 3 of the 4 children had impairment of humoral as well as cell-mediated immunity, it is suggested that the intestinal disease in each was more related to the defect in cellular immunity. The presence of "foamy" macrophages containing numerous pleomorphic inclusions suggests the possibility of a macrophage abnormality. Since large vacuolated macrophages have been described in Whipple's disease and in chronic granulomatous disease, the possibility of a common thread of defective host defense and gastrointestinal malfunction in these 3 conditions is suggested.

7811 MASSIVE GASTROINTESTINAL HEMORRHAGE FROM A CARCINOID TUMOR OF THE ILEUM: REPORT OF A CASE. *(E.)* Burney, R. E.; Standard, J. E. (Yale-New Haven Med. Ctr., Conn.). *Conn. Med.* 38(9):457-458, 1974.

Acute, massive hemorrhage was the presenting symptom in a 71-yr-old man with a carcinoid tumor of the ileum. The patient's history included hypertension and cardiomegaly; he had been taking digoxin (0.25 mg/day) as his only medication. Transfusions of whole blood and packed cells were begun. Upper gastrointestinal series and barium enema were within normal limits, as was sigmoidoscopy. A selective superior mesenteric arteriogram did not locate the site of bleeding. Abdominal exploration showed gross blood present in the mid-ileum, throughout the rest of the small bowel, and in the colon. A 1-cm tumor mass was manually located on the antimesenteric border of the mid-ileum, causing visible kinking of the small bowel wall at that point. Segmental resection was performed followed by resection of a wider area of the small bowel and mesentery when the diagnosis of carcinoid tumor was made. It is stressed that a careful, methodical palpation of the small bowel is essential in a case of gastrointestinal bleeding of undetermined origin.

7812 ARTICULAR COMPLICATIONS IN OBESE PATIENTS AFTER JEJUNOCOLIC BYPASS. *(E.)* Mir-Madjlessi, S. H.; Mackenzie, A. H.; Winkelman, E. I. (Cleveland Clin., Ohio). *Cleve. Clin. Q.* 41(3):119-126, 1974.

Jejunocolic shunt was performed on 27 patients (19 women and 8 men, aged 22-47 yr) for massive obesity. The jejunum was transected 76 cm from the ligament of Treitz. The proximal end was anastomosed end-to-side to the mid-transverse colon, in one case to the ascending colon. In 15 cases the distal jejunum was brought to the abdominal wall. A silastic tube was secured to it, making a jejunostomy available for fluid and electrolyte replacement. Six patients died 10 days to 62 months after surgery. Thirteen patients had take-down of their jejunocolic shunts 9 to 135 months postoperatively. Weight loss was particularly marked in the 12th to 18th month postoperatively. Postoperative complications included dehydration, electrolyte imbalance, hypocalcemia, hypomagnesemia, hypoprothrombinemia, postural hypotension, tetany, joint symptoms, anemia, cholelithiasis, and nephrolithiasis. Liver abnormalities included fatty metamorphosis, nutritional cirrhosis, and fatal hepatic failure. Articular symptoms developed in 8 patients (7 women and 1 man) as early as 2 months and as late as 33 months postoperatively. Joints with pain or synovitis were: ankles in 8 patients, wrists in 7, knees in 7, hips in 6, shoulders in 5, fingers in 5, elbows in 4 and neck in 1. Objective findings of arthritis were present in only 4 patients. Migratory polyarthralgias associated with chills and fever appeared in 2 patients; 3 also had diffuse myalgias. The duration of symptoms varied from 3 to 23 months. The course of joint disease was benign in all patients and without any residual deformity. Synovial fluid obtained from 2 patients was noninflammatory. The arthralgias were modified with analgesic treatment, but 2 patients required ACTH or corticosteroids to relieve arthritic manifestations. In 1 patient the arthritic pain was relieved only after take-down of the shunt. In 2 others restitution of the normal bowel continuity for other reasons resulted in the disappearance of symptoms.

7813 CYTOLOGICAL FINDINGS IN CHRONIC NON-SPECIFIC DUODENITIS. *(E.)* Cheli, R.; Aste, H.; Nicolo, G.; Ciancamerla, G. (San Martino Hosp., Genoa, Italy). *Endoscopy* 6(2):110-115, 1974.

Duodenal histological and cytological specimens from 28 patients (18 men and 10 women, aged 18-68 yr) with chronic nonspecific duodenitis and 20 controls (12 men and 8 women, aged 22-45 yr) were obtained with a 2-way abrasive tube. Of the patients with nonspecific chronic duodenitis, 7 had irritable colon, 4 had chronic pancreatitis, 8 had hiatal hernia, and 9 complained of upper dyspeptic symptoms without demonstrable pathology. The cytological material from these patients showed abundant inflammatory cells, particularly lymphocytes, plasma cells, histocytes and neutrophils. Enterocytes showed shortened longitudinal diameter with values around 16-18 μ. The brush border was thinner or had disappeared. Cytoplasm contained opically empty vacuoles which incised and divided remaining protoplasmic material. The goblet cells were numerically increased and showed signs of a sharp activity. The mucoid cells were numerically increased, but did not reveal particular morphological differences in comparison with the cells present in normal mucosa. The cytological findings were in accord with the histological picture of duodenitis, especially atrophic duodenitis, where cytological alterations were consistently present. The abnormalities were also seen frequently (70% of cases) in superficial duodenitis. The results indicate that cytology is a useful tool in the diagnosis of duodenitis.

7814 DELAYED INTUSSUSCEPTION. *(E.)* Ginzburg, L.; Friedman, I. H. (Beth Israel Med. Ctr., New York, N.Y.). *N.Y. State J. Med.* 74(11): 2009-2013, 1974.

Case histories are presented for 3 of 8 patients with clinical evidence of subacute or chronic intestinal obstruction subsequent to apparently uncomplicated removal of a long intestinal tube used for treatment of nonstrangulating obstructions of the small intestine. The outstanding symptoms were vomiting and intestinal cramps. Distention was not remarkable. A Cantor (single lumen) tube was used for management of the obstruction in all 3 cases. In 1 of 2 patients with continuous Cantor-tube drainage, barium study demonstrated definite jejunal obstruction. Eight weeks earlier a Miller-Abbot (double lumen) tube had been passed through this patient prior to a left hemicolectomy for a neoplasm of the large intestine. In the 2nd patient, barium study after laparotomy showed obstruction of the distal duodenum but did not preclude the possibility of a superior mesenteric artery syndrome. Exploration of both patients revealed an antegrade jejunojejunal intussusception which was resected. In the 3rd patient, the Cantor tube was inserted prior to a right hemicolectomy for a leiomyoma of the terminal ileum. A diatrizoate study on the 6th postoperative day showed no obstruction and the patient was discharged. Upon readmittance 11 days postdischarge, abdominal x-rays revealed numerous dilated loops of small intestine. A diatrizoate study after insertion of a Cantor tube showed prompt passage of contrast material but persistence of a dilated proximal loop. The patient was explored and an antegrade jejunal intussusception was found. None of these intussusceptions could be completely reduced due to the presence of fibrinous adhesions. The pathological basis for the observed obstruction was the development of a propulsive, isoperistaltic, irreducible intussusception induced by the intestinal tube itself.

7815 VITAMIN B_{12} DEPLETION IN OBESE PATIENTS TREATED WITH JEJUNOILEAL SHUNT. *(E.)* Juhl, E.; Bruusgaard, A.; Hippe, E.; Korner, B.; Quaade, F.; Baden, H. (Frederiksberg Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(6):543-547, 1974.

In 10 obese patients treated with intestinal bypass (37 cm of proximal jejunum anastomosed end-to-side to 13 cm of distal ileum), serum vitamin B_{12} gradually declined from a preoperative value of 450 ng/liter to 160 ng/liter after 24 months. During the same 2-yr period intestinal absorption of vitamin decreased as evaluated by the Schilling test. Stimulation of gastric secretion with histamine revealed normal production of acid and intrinsic factor. In serum the B_{12}-binding capacity was normal, and no intrinsic factor antibody could be demonstrated. In another group of 5 patients, quantitative cultures from the proximal jejunum showed an abnormal amount of bacteria. The abnormal proliferation of bacteria, predominantly *E. coli*, was confirmed by the postoperative appearance of deconjugated bile acids in duodenal aspirate. Schilling test values in these 5 patients fell markedly after the bypass operation but rose after 4 days of treatment with tetracycline. The results indicate that the vitamin B_{12} depletion was due not only to a reduced absorptive capacity in the remaining ileum but also to the appearance of intestinal bacteria utilizing vitamin B_{12}. A supplement of parenteral vitamin B_{12} is mandatory in this type of bypass operation.

7816 HISTOPATHOLOGICAL AND RADIOLOGICAL APPEARANCES OF DUODENUM IN GIARDIASIS. *(E.)* Nath, S.; Sehgal, A. K.; Chawla, L. S.; Chhuttani, P. N.; Broor, S. L. (Postgrad. Inst. Med. Educ. Res., Chandigarh, India). *Indian J. Med. Res.* 62(5):719-725, 1974.

Twenty-three patients with giardiasis in whom the parasite was demonstrated in stools as well as in the duodenal aspirate were studied to detect pathological changes in the duodenum. Duodenal biopsy was done by Rubin's multipurpose intestinal biopsy tube from the third part of the duodenum under fluoroscopic control. Non-flocculating barium was used for the radiological examination of the duodenum. Biopsy of giardiasis patients revealed normal villi in 10 cases, while Grade I change was detected in 8 and Grade II in 5 cases. In no case was Grade III change observed. Increased mitotic figures were noted in both the grades but were more associated with Grade II change. Determinations of the height of villi, depth of crypts, villous crypt ratio, total mucosal thickness, epithelial height, cellular infiltration in lamina propria and mitotic index showed statistically significant difference only in the values of mitotic index and cell count in the lamina propria which were both increased in the giardiasis group. Radiological study showed that 12 cases (52.5%) had increased mucosal fold thickness. Increased duodenal hurry and irritability was noted in 17 cases (73.9%) and in some it was so marked that despite repeated attempts, no picture of the duodenal bulb could be taken. After successful treatment, only 5 patients (21.7%) showed abnormal mucosal fold thickness and only 3 patients (13%) showed increased duodenal irritability. There was a statistically significant negative correlation between the histological and radiological appearances. As the height of the villi decreased, the mucosal fold thickness increased. It is suggested that *Giardia* can cause morphological abnormalities amounting to duodenitis.

7817 NUTRITIONAL ADAPTATION AFTER SMALL BOWEL RESECTION IN RATS.

(E.) Young, E. A.; Weser, E. (Univ. Texas Med. Sch., San Antonio). *J. Nutr.* 104(8):994-1001, 1974.

Body weight, growth rate, energy intake and energy efficiency were measured in male Sprague-Dawley rats with a 50% resection of either the distal (8 rats) or proximal (5 rats) small intestine, and correlated with adaptive weight changes in the remaining bowel. The weights of unoperated controls (12 rats) were significantly greater than sham-operated (6 rats) or resected rats during weeks 1-3 following operation. However, the rate of weight gain for operated animals was greater during these 3 weeks, suggesting an adaptive response whereby operated rats used calories more efficiently thus compensating for reduced energy intake during the week of surgery as well as for physiological stress. This increased energy efficiency could also result from diversion of energy from activity to tissue regeneration. Proximally resected rats continued to show greater energy efficiency through week 4, after which all 4 groups had similar energy efficiency. Energy intake of all operated rats was reduced 25% during the week after surgery. By the second week, energy intake was similar in all groups. When energy intake is compared between operated groups, distally resected rats consistently consumed more energy than proximally resected rats between weeks 3 to 9. At 8 weeks, distally resected animals consumed greater energy intake than any other group, indicating an important difference in adaptation. Distally resected animals may require greater ingestion of calories to maintain a normal growth pattern. When bowel dry weights/cm length were compared in all groups, hyperplasia was noted in distal remnants of proximally resected rats, which may be related to an increased nutrient load presented to this region of the gut. The significant hyperplasia of this region of the bowel provided enhanced absorption and allowed a growth pattern comparable to control animals to be maintained. This adaptation may be diminished by controlling food intake to smaller nutrient load cycles/unit of time, or by providing total energy requirements by i.v. alimentation. Normal growth is primarily achieved by greater caloric intake in distally resected rats, and probably enhanced absorption by the hyperplastic distal remnant in proximally resected animals.

7818 EXTERNAL PANCREATIC FUNCTION FOLLOWING THREE TYPES OF INTESTINAL SHUNT OPERATION FOR OBESITY.

(E.) Dano, P.; Lenz, K. (Rigshosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(5):451-455, 1974.

Intestinal shunt operations were performed as a treatment for morbid obesity in 36 patients. The external pancreatic function following a stimulation meal was investigated before surgery, 6-12 and 12-24 months after operation. In each patient 48 cm of small intestine was preserved, but the ratio of functioning jejunum/ileum was different: Type I 36 cm/12 cm; Type II 24 cm/24 cm; and Type III 12 cm/36 cm. The pancreatic function decreased in all 3 types during the first postoperative period. The reduction was least in Type III operated patients. In the second postoperative period there was an increase in pancreatic function in Type I and II operated patients, but a sustained reduction in Type III operated patients. It is suggested that the reduction of pancreatic function in the first postoperative period was due to malabsorption, and the sustained reduction in Type III operated patients in the second postoperative period was due to impaired release of stimulating hormones from the bypassed jejunum. The results indicate that a significant, but transient, reduction of pancreatic function regularly occurs after therapeutical intestinal bypass.

7819 CALCIUM ETHYLENEDIAMINETETRAACETATE TOXICITY IN THE RAT: SEQUENTIAL LIGHT- AND ELECTRON-MICROSCOPIC STUDIES ON CHELATE-INDUCED ENTEROPATHY.

(E.) Braide, V. B. C.; Aronson, A. L. (New York State Vet. Coll., Cornell Univ., Ithaca). *Toxicol. Appl. Pharmacol.* 30(1):52-62, 1974.

The effects of calcium ethylenediaminetetraacetate (CaEDTA) infusion on small intestinal morphology and permeability were studied in 27 Long-Evans rats (including 11 controls). All rats were infused i.v. for a total of 72 hr. Rats treated with CaEDTA received the drug for the last 12-48 hr (following infusion of a 0.9% NaCl solution), at a rate of 6 mM/kg/24 hr. Light microscopy of small intestinal tissue revealed degenerative changes in duodenal crypt cells; electron microscopy revealed high-amplitude swelling of mitochondria as early as 12 hr following the start of CaEDTA infusion. The mitotic index and cell population density was markedly diminished by hour 24. At this time the villus structure was still intact. Enhanced permeability of the intestine to ^{51}Cr labeled CaEDTA occurred between 24 and 36 hr and correlated with the loss of villous epithelium. This study supports the work of others suggesting that inhibition of DNA synthesis is an important biochemical lesion in CaEDTA-induced enteropathy. The occurrence of high-amplitude mitochondrial swelling suggests that interference with the energy supply in the cell may be a contributing factor toward inhibition of the synthesis of DNA.

7820 ANAEROBIC BACTERIA AND DECONJUGATED BILE SALTS IN THE UPPER SMALL INTESTINE OF INFANTS WITH GASTROINTESTINAL DISORDERS. *(E.)* Challacombe, D. N.; Richardson, J. M.; Edkins, S. (Inst. Child Hlth., Univ. Birmingham, England). *Acta Pediatr. Scand.* 63(4):581-587, 1974.

Deconjugated bile salts have been reported in the upper small intestine of infants with protracted diarrhea and secondary monosaccharide intolerance. As deconjugated bile salts inhibit monosaccharide transport mechanisms in the small intestine of experimental animals both *in vivo* and *in vitro*, they may also cause monosaccharide malabsorption in these infants. In this study, 30 infants and children were divided into 3 clinical groups: 1) 7 infants with chronic diarrhea; 2) 7 postsurgical infants; and 3) 16 infants and children with other gastrointestinal disorders. The infants were challenged with oral sugar loads to detect patients with glucose or lactose intolerance. The duodenal juice of all infants with protracted diarrhea was examined by thin layer chromatography and fluorimetry for deconjugated bile salts and cultured anaerobically for bacteria with known deconjugating properties. In addition, duodenal juice from infants and children from group 3 was similarly studied. Deconjugated bile salts and obligate anaerobic bacteria were associated in only 2 out of 30 samples of duodenal juice, 1 from an infant with secondary lactose intolerance, and 1 from an infant with unexplained failure to gain weight. The absence of deconjugated bile salts in the duodenum of 2 infants with secondary monosaccharide intolerance and from other infants with protracted diarrhea does not support the suggestion that the action of deconjugated bile salts on the small intestinal mucosa is an important causative factor in these disorders.

SMALL INTESTINE

Malabsorption

7840 HL-A8 AND THE IMMUNE RESPONSE TO GLUTEN. *(E.)* Scott, B. B.; Rajah, S. M.; Swinburne, M. L.; Losowsky, M. S. (St. James's Hosp., Leeds, England). *Lancet* (7877):374-377, 1974.

Serum antibodies to gluten and milk were correlated with the presence of the histocompatibility antigen HL-A8 in 124 patients and healthy controls. The patients were diagnosed as follows: cirrhosis (22), chronic active hepatitis (17), other liver disease (11), definite celiac disease (15), probable celiac disease (8), malabsorption (9), glomerulonephritis (5), Crohn's disease (5), chronic pancreatitis (4), ulcerative colitis (3), ankylosing spondylitis (1), and sarcoidosis (1). Gluten antibodies were present at significantly higher titer in the HL-A8 positive subjects. Of the 58 HL-A8 positive subjects, 15 (26%) had gluten antibodies at a titer greater than 1/128 compared with only 2 (3%) of the 66 HL-A8 negative subjects. Patients with celiac disease had the highest antibody titers to gluten, although most were on a gluten-free diet. Among the nonceliac subjects, high gluten antibody titers were mainly confined to patients with cirrhosis or chronic active hepatitis. There was a tendency for milk antibodies to be higher in subjects who were HL-A8 negative. Taking both types of antibody together gave a very good discrimination between HL-A8 negative and HL-A8 positive subjects. These results show that in man the HL-A system is related to the pattern of immune response to certain dietary antigens.

7841 AN EVALUATION OF PREDNISOLONE, TETRACYCLINE AND HIGH PROTEIN DIET FOR THE THERAPY OF IDIOPATHIC TROPICAL MALABSORPTION SYNDROME. (ITMS). *(E.)* Tandon, B. N.; Bose, S. L.; Saikia, B. (All India Inst. Med. Sci., New Delhi). *Indian J. Med. Res.* 62(5):704-711, 1974.

Five patients with idiopathic tropical malabsorption syndrome received a high-protein diet and tetracycline (250 mg, 4 times/day) for 6 weeks. An additional 9 patients with idiopathic tropical malabsorption syndrome received a high-protein diet with tetracycline (1 g/day for 2 weeks) and prednisolone (30 mg/day for the 1st week, 20 mg/day for the 2nd week, and 10 mg/day for the subsequent 4 weeks). The 5 patients receiving tetracycline and diet therapy showed clinical improvement with a feeling of well being, increased appetite, decreased frequency of bowel movements and improvement in the character of stool, and an average 3 kg gain in weight. D-xylose, abnormal in all 5 before treatment, became normal in 2 cases. None of 4 patients with steatorrhea reverted to normal, although fat absorption improved. One of 3 patients with abnormal jejunal histology reverted to normal; the remaining 2 showed improvement. The mitochondrial marker enzyme succinic-dehydrogenase, reduced in 4 patients, showed no improvement. The 9 patients receiving diet, tetracycline, and prednisolone, showed striking clinical recovery and an average weight gain of 5 kg. The intestinal absorption functions greatly improved. D-xylose excretion normalized in 7 of 8 patients. Of 7 patients with steatorrhea, 2 acquired normal fat absorption. Vitamin B_{12} malabsorption normalized in 3 of 4 cases. However, 2 patients who had normal vitamin B_{12} absorption at the start of treatment showed poor absorption at its conclusion. Only 1 of 6 patients with abnormal jejunal biopsy recovered to normal. Brush-border enzyme, alkaline phosphatase, was reduced in 2 patients and improved in each. Succinic-dehydrogenase did not show recovery in any patient. Thus, treatment with high-protein diet and tetracycline resulted in a partial recovery. Addition of prednisolone resulted in a better clinical recovery and more significant improvement of absorptive functions. However, neither regimen cured the disease. Idiopathic tropical malabsorption syndrome may be an immune deficiency disease which allows bacterial colonization in the small bowel with consequent clinical and biochemical features of malabsorption.

7842 APATHETIC THYROTOXICOSIS CAUSING GASTROINTESTINAL MALABSORPTION. *(E.)* Sheehy, T. W.; Allison, T. M. (Univ. Alabama Sch. Med., Birmingham). *JAMA* 230(1):69-71, 1974.

A 52-yr-old black woman with a 26-yr history of diabetes mellitus was hospitalized complaining of intermittent diarrhea for 3 months. Over the previous 18 months her weight dropped from 120 to 60 lb. despite a good appetite. During this weight loss her diabetes became less difficult to control and she stopped taking insulin. Proctosigmoidoscopy, barium enema, barium swallow with small intestine follow-through, and an x-ray film series of the gallbladder were normal. Increased gastrointestinal motility was demonstrated by the appearance of contrast material in the ileocecal area within 15 min of ingestion and by continuous repetitive type II gastric waves. A small-bowel biopsy specimen was normal. Bacterial cultures of jejunal aspirates did not yield significant growth. No fecal pus cells or parasites were seen. Steatorrhea remained massive even when dietary fat intake was restricted to 100 g or less/day. Substitution of dietary medium-chain triglycerides, which are absorbed directly from the lumen without need of hydrolysis, bile salts, or intracellular reconstitution, led to considerable reduction in both steatorrhea and fecal fluid loss. Pancreatic insufficiency or thyrotoxicosis was suspected due to tachycardia, apathy, hurried intestinal transit, and absence of a jejunal lesion. No improvement occurred with pancreatic replacement therapy and a secretin test was normal. Thyroid function tests led to the diagnosis of thyrotoxicosis. Appropriate therapy for thyrotoxicosis (50 mg 3,5,3'-triiodothyronine, 3 times/day followed by Na ^{131}I (6 mC p.o.) led to return of normal intestinal function and resurgence of diabetic symptoms requiring use of insulin.

7843 MULTIPLE JEJUNAL STRICTURES ASSOCIATED WITH MEGALOBLASTIC ANAEMIA AND MYELOPATHY. *(E.)* Elsborg, L. (Arhus County Hosp., Denmark). *Acta. Med. Scand.* 196(1-2):127-131, 1974.

An exploratory laparotomy was performed on a 26-yr-old male due to a 10-yr history of continuous progression of his symptoms, including malabsorption and neurological defects suggestive of subacute combined degeneration of the spinal cord. The laparotomy revealed an intestinal stenosis situated about 75 cm distal to the Trietz ligament, followed by a dilated segment and then by another stenosis. Proximal to the stenosed segments the jejunum and duodenum were markedly dilated. The intestinal wall was hypertrophied, and the segment showed vigorous peristalsis. The stenosed portions of the intestine, 35 cm in length, were resected, and an end-to-end anastomosis between the normal appearing jejunum and the dilated proximal intestinal segment was carried out. In spite of optimal substitution therapy with vitamin B_{12} prior to surgery, the bone marrow was megaloblastic, which was ascribed to folate deficiency resulting from malabsorption of folic acid. A possible association between neurological lesions and folate deficiency was not established for there may also have been a deficiency of other nutritional factors of significance for nervous tissues. The malabsorption syndrome associated with multiple strictures of the jejunum carries a grave prognosis and may lead to severe disability of the patient. The treatment of choice is surgical resection.

7844 IDIOPATHIC HYPOPARATHYROIDISM AND STEATORRHEA: A NEW AID IN MANAGEMENT. *(E.)* Lorenz, R.; Burr, I. M. (Vanderbilt Univ. Sch. Med., Nashville, Tenn.). *J. Pediatr.* 85(4):522-525, 1974.

Metabolic studies of fat and calcium balance and details of successful therapy are described for a white female patient with hypoparathyroidism and hypocalcemia associated with steatorrhea. At 6 yr of age idiopathic hypoparathyroidism was diagnosed. Therapy was started with vitamin D, 50,000 U and calcium lactate, 900 mg/day with normal serum calcium levels. Evidence of malabsorption became apparent at age 13. Stool fat excretion was approximately 7% of intake. Liver functions were mildly abnormal: SGPT 150 KU, serum bilirubin 1.8 mg/100 ml. Vitamin D dosage was increased (200,000 U/day) and accompanied by calcium (3 g/day) and oral supplements of magnesium acetate (500 mg/day). Within 2 weeks recurrent carpopedal spasm prompted hospital readmission; hypocalcemia and steatorrhea were present. Both proved difficult to manage, suggesting that patients with steatorrhea and hypoparathyroidism with hypocalcemia may enter a phase whereby low concentrations of serum calcium predispose to further steatorrhea which in turn aggravates the hypocalcemia. A beneficial effect on fat balance was achieved immediately after institution of a medium-chain triglyceride diet containing 50% of fat by weight. At this time calcium balance became positive. This diet was used on the theory that fat given as medium-chain triglycerides, requiring no intraluminal digestion for absorption, would reduce fecal fat losses and thus calcium losses secondary to saponification. The medium-chain triglyceride diet appears to contribute to the relatively rapid decrease in the need for parathormone, vitamin D, and calcium supplements. Thus, while maintenance of normal serum calcium levels alone may be sufficient to break the cycle of hypocalcemia aggravated by steatorrhea, the additional use of a diet containing medium-chain triglycerides appears to be an aid in management.

7845 COEXISTENCE OF DIABETES MELLITUS AND CELIAC DISEASE. *(E.)* Thain, M. E.; Hamilton, J. R.; Ehrlich, R. M. (Hosp. Sick Children, Toronto, Canada). *J. Pediatr.* 85(4):527-529, 1974.

A study was made of 6 children, hospitalized for the diagnosis and early care of either diabetes mellitus or celiac disease. Of the 6 children, 5 were known to have diabetes before celiac disease was diagnosed, but in retrospect they all had subtle intestinal symptoms dating back at least to the onset of diabetes. The clinical manifestations of celiac disease were common to all: foul, bulky stools; episodic diarrhea; abdominal distention; anorexia; and poor weight gain. All children had normal concentrations of serum cholesterol, triglycerides, and lipoproteins. Steatorrhea with fat excretions of 10-54% of dietary intake was present in 5; 1 patient excreted only 8% of dietary fat. Biopsy of the intestinal mucosa was typical of celiac disease, as was clinical response to dietary therapy. After treatment with a gluten-free diet, the intestinal symptoms improved rapidly and all children gained weight. Fat absorption was reassessed in 3 children and found to be normal. Control of diabetes improved and the number and severity of hypoglycemic episodes declined. Insulin requirement increased in 4 children as absorptive function improved in response to diet. The occurrence of diabetes in approximately 6% of 112 children with celiac disease and the appearance of celiac disease in about 1.5% of 400 cases of diabetes mellitus over an 8 yr period suggests the coexistence of these diseases in children is far greater than in the general population. It is suggested that the two conditions may have a common etiology through an immune factor.

7846 IMMUNOLOGICAL STUDIES OF THE JEJUNAL MUCOSA IN NORMAL SUBJECTS AND ADULT CELIAC PATIENTS.

(E.) Gasbarrini, G.; Miglio, F.; Serra, M. A.; Bernardi, M. (Inst. Special Med. Pathol. Clin. Methodol., Univ. Bologna, Italy). *Digestion* 10:122-128, 1974.

The number of plasma cells containing each of the three principal types of immunoglobulins (IgA, IgG, IgM) in the human jejunal mucosa was determined in 8 adult celiac patients (aged 25-45 yr) and in 8 subjects without any gastrointestinal abnormalities, using immunofluorescent techniques. A statistical comparison of the results showed a particularly significant increase in IgM cells and a less significant increase in the IgG cells in celiac disease. A decrease of the IgA cells was also noted, but was not statistically significant. It is suggested that the decrease in IgA cells may be related to phenomena associated with alterations of the interstitial area, such as edema. The marked increase in IgM cells is extremely significant in that an isolated increase in IgM cell concentration in the jejunum has not yet been determined for any other disease. Further, IgM cell increases have not been identified in other diseases with an immunological etiology. A very high IgG cell count and simultaneously a low IgM count was noted in one particular celiac patient who was not responding to gluten-free diet and who showed serious degradation of the jejunal mucosal structure. A year later, autopsy revealed this patient had intestinal lymphosarcoma and thus suggested a possible connection between a high IgG count coupled with a low IgM count and pre-clinical lymphosarcoma. Similar immunoglobulin cell counts have been found in 2 additional cases of lymphosarcoma associated with celiac disease.

LARGE INTESTINE

7853 PREOPERATIVE USE OF ANTIBIOTICS IN COLONIC SURGERY.

(E.) Bridoux, M. (Good Samaritan Hosp. Med. Ctr., Portland, Ore.). *Dis. Colon Rectum* 17(4):487-492, 1974.

A retrospective study of 100 cases of elective colonic surgery was conducted to determine the effectiveness of preoperative antibiotic therapy. Mechanical preparation (restrictive diet and/or laxatives and/or enemas) was given to 98 patients while 80 received preoperative antibiotics (oral and/or systemic). Complications (wound infection, abscess or peritonitis, anastomotic leak or fistula, wound dehiscence, enterocolitis, renal failure, and death or tumor recurrence) occurred postoperatively in 19 patients, with 6 patients having more than one complication; 3 patients died. No complication occurred in patients less than 51 yr old. Of the 20 patients who did not receive preoperative antibiotics, only 1 developed a wound infection, as compared to 18 of 80 (22%) patients who had received an antibiotic plus mechanical preparation. It appears that continued use of conventional preoperative antibiotic preparations for elective colonic surgery is unjustified.

7854 THE EFFECTS OF LOW AND HIGH RESIDUE DIETS ON THE RATE OF TRANSIT AND COMPOSITION OF THE FECES. *(E.)* Parks, T. G. (Dept. Surg., Queen's Univ., Belfast, Northern Ireland). *Proc. Int. Symp. Gastrointest. Motility, 4th, 1973,* pp. 369-380.

A technique utilizing ^{51}Cr-labeled sodium chromate and radiopaque pellets has been used to study intestinal transit times in 24 patients with diverticular disease of the colon maintained on a low or high residue diet. Mean transit times were essentially the same, whether estimated with ^{51}Cr-sodium chromate or using radiopaque pellets. When the radiopaque pellet was used, the mean transit rate of patients on a high residue diet was significantly ($P < 0.01$) greater than that of patients on a low residue diet. Patients on the high residue diet also have a greater average stool dry weight (24.3 gm) than did those on the low residue diet (19.7 gm). The frequency of defecation as well as the mean fecal fat excretion were the same for both high and low residue diets.

7855 GASTRIC LESION OF FAMILIAL POLYPOSIS COLI. *(E.)* Utsunomiya, J.; Maki, T.; Iwama, T.; Matsunaga, Y.; Ichikawa, T.; Shinomura, T.; Hamaguchi, E.; Aoki, N. (Tokyo Med. Dental Univ., Japan). *Cancer* 34(3):745-754, 1974.

Fifteen cases of familial polyposis coli occurring in 6 different unselected families were studied. The incidence of gastric polyps among these patients was determined. Clinical studies such as roentgenogram and endoscopic examinations were carried out in 12 cases, the resected stomach was examined in 2, and autopsy material was used in 2. Elevated lesions were found in the stomachs of 10 subjects (66.7%). This was a much higher incidence than that found in a nationwide survey of this disease in Japan (10%). Thus, this disease may not necessarily be localized to the large intestine, and the absence of gastric polyps in other case reports is probably due to insufficient examination of the stomach. It is suggested that these findings could also be influenced by an environmental factor is Japan.

7856 VILLOUS ADENOMA OF THE COLON AND RECTUM: AN ULTRASTRUCTURAL STUDY. *(E.)* Ioachim, N. J.; Delaney, W. E.; Madrazo, A. (St. Vincent's Hosp. Med. Ctr., New York, N.Y.). *Cancer* 34(3):586-596, 1974.

The villous component of 9 human colonic polyps (3 pure villous adenoma and 6 mixed adenomatous and villous adenomas) was studied by light and electron microscopy. Normal colonic mucosa was used as a control. The predominant cell was an undifferentiated epithelial cell resembling those of the base of the crypts in normal colonic mucosa. A minority of these cells differentiated toward goblet cells and absorptive cells. Interdigitations of the plasma membrane with enlarged intercellular spaces were frequently observed and may be related to the loss of water and electrolytes in some of these tumors, suggesting an analogy to changes in the renal tubular plasma membrane in kaliopenic nephropathy. Numerous membrane-bound inter- and intracellular "inclusion bodies" representing degenerated lymphocytes and epithelial cell organelles were commonly found. Viral inclusions were not detected in this material. It appears unlikely that the inclusion bodies observed in villous adenoma represent lysosome-modified vesicles, secondary to absorption of protein and surface mucosubstances.

7857 CARCINOID TUMORS OF THE RECTUM: EXPERIENCE WITH 38 CASES. *(E.)* Grablowsky, O. M.; Ribaudo, J. M.; Ray, J. E. (Ochsner Clin. Ochsner Fdn. Hosp., New Orleans, La.). *Dis. Colon Rectum* 17(4):532-535, 1974.

The clinical and pathologic characteristics of carcinoid tumors of the rectum were studied in 38 patients (25 men and 13 women, aged 28-81 yr) diagnosed and treated over a 23 yr period. Clinically benign tumors were found in 33 patients and 5 had invasive carcinoids with metastasis to regional lymph nodes or the liver. All benign tumors were completely asymptomatic and were discovered on routine rectal and proctoscopic examinations. All patients with malignant tumors had symptoms. Associated rectal tumors (cloacogenic carcinoma and familial polyps) were found in 2 patients. The distinction between carcinoids which are clinically benign and those which are malignant can be made only by determining the extent of invasion of the bowel wall or by evidence of metastasis. The gross size of the tumor is important, since most tumors less than 2 cm in diameter are localized, whereas those 2 cm in diameter or larger are invasive and metastasize. Benign rectal carcinoids should be treated with biopsy and thorough fulguration or local excision. However, invasive tumors should be treated by radical resection whenever possible, since the metastatic lesions are very slow-growing and the patient may remain relatively asymptomatic for long periods.

7858 THE ANATOMICAL PRECURSOR OF COLORECTAL CARCINOMA. *(E.)* Fenoglio, C. M.; Lane, N. (Coll. Physicians Surg., Columbia Univ., New York, N.Y.). *Cancer* 34(3)suppl.:819-823, 1974.

Hyperplastic polyps account for about 90% of all "polyps." They are not neoplasms and are unrelated to either adenomas or carcinomas. Adenomas, which are only 1/10 as common, may occur grossly as adenamatous polyps or papillary adenomas. Whether they are large or small, pedunculated, sessile, or flat, they are true non-invasive neoplasms. Depending on size and probably because of a sessile mode of growth, intramucosal carcinoma and/or "early" invasive cancer may be observed in adenomas. On the other hand, "early" cancer, defined as intramucosal carcinoma with or without microinvasion, does not seem to occur unassociated with adenoma. Since colorectal carcinoma is so common, many examples of "early" cancer should be found if the majority of ordinary adenocarcinomas arose directly from normal crypts of Lieberkühn. The apparent nonexistence of small foci of intramucosal carcinoma, with or without microinvasion, in normal mucosa, and their frequency in adenomas, are two fundamental pathologic facts. They seem to disprove the proposition that cancer cells ordinarily arise *de novo* from the normal cells of the crypt of Lieberkühn without the interposition of a stage in the neoplastic process that is recognized as adenoma.

7859 PROCTOSIGMOIDOSCOPY AND POLYPECTOMY IN REDUCING THE INCIDENCE OF RECTAL CANCER. *(E.)* Gilbertsen, V. A. (Univ. Minnesota Med. Ctr., Minneapolis). *Cancer* 34(3)suppl.:936-939, 1974.

Results of a 25 yr study involving periodic proctosigmoidoscopy on 18,158 patients are presented. Apparently benign polyps or adenomas were removed when detected. Although 75-80 cancers would be expected to develop in this group of patients over this period, only 11 were observed. Each was detected while still localized within the bowel wall. Six of the 11 were mucosal without invasion, and in all but 1 there was no apparent involvement of the cancer deeper than the submucosa. Each was resected and no recurrences have been observed on follow-up. One patient died postoperatively at another hospital after segmental resection for a low sigmoid cancer. Another died 4 yr after surgery of a second cancer, primary in the common bile duct, without evidence that bowel cancer had recurred. Except for 1 patient, who has been followed for 3 yr, the remaining patients are 5-yr survivors and are apparently free of cancer. It is suggested that periodic proctosigmoidoscopy of high-risk patients could nearly eliminate lower bowel cancer as a cause of death at a cost which would be approximately the same as that presently required to treat patients with the disease.

7860 ASPECTS OF THE EPIDEMIOLOGY OF DIVERTICULAR DISEASE AND ISCHEMIC HEART DISEASE. *(E.)* Trowell, H.; Painter, N.; Burkitt, D. (Med. Sch., Makarere Univ., Uganda). *Am. J. Dig. Dis.* 19(9): 864-873, 1974.

Diverticular disease of the colon is common in populations where the intake of cereal fiber in the diet has been reduced dramatically for several decades. It has been shown that the addition of fiber in the form of wheat bran relieves the symptoms of the uncomplicated forms of the disease. It has been suggested that a deficiency of dietary fiber may play an etiologic role in ischemic heart disease. Data from the literature as well as from questionnaires sent to 170 hospitals in Africa, India and Pakistan have been used to study the geographic distribution of and association between diverticular disease and ischemic heart disease. Although the incidence of these diseases is not known accurately in many countries, it is evident from available data that the 2 are associated both clinically and geographically, often appearing together in the same patient. In more primitive societies, such as Africa, where fiber content of the diet remains high, the incidence of these 2 diseases has remained low; the incidence of diverticular and ischemic heart disease in the higher socioeconomic groups in these countries, who have begun to consume a low fiber content diet, has, however, begun to increase. It is suggested that fiber deficiency may help to cause not only diverticulosis, but also ischemic heart disease.

LARGE INTESTINE

Ulcerative Colitis

7914 FLUORESCENT ANTI-COLON ANTIBODIES AND INFLAMMATORY EOSINOPHILIA IN ULCERATIVE COLITIS. *(E.)* Marcussen, H. (Gentofte Univ. Hosp., Hellerup, Denmark). *Scand. J. Gastroenterol.* 9(6):575-577, 1974.

The occurrence of colon-related circulating antibodies in 119 consecutive cases of ulcerative colitis (68 women and 51 men) was investigated with the indirect immunofluorescent method. Circulating antibodies were found in 19% of the patients (15 women and 8 men). Eosinophilia was detected in colonic mucosal exudate in 45% (36 women and 18 men) on semiquantitative cytological examination. The frequency of eosinophilia (78%) in patients with circulating anticolon antibodies was significantly greater than in the total patient group. This correlation may reflect a subepithelial cytological reaction: antigen-antibody complexes are thought to be formed subepithelially in the lamina propria where the cytologic reaction of inflammation appears, while eosinophilic granulocytes have an important role in experimental and clinical inflammations. During sigmoidoscopy, the macroscopic appearance of the rectal mucosa was classified as inactive, moderately active, or active. Inactive and active cases differed significantly with respect to the presence of eosinophilia but not with respect to anticolon antibodies.

7915 ENEMA VOLUME AS AN IMPORTANT FACTOR IN SUCCESSFUL TOPICAL CORTICOSTEROID TREATMENT OF COLITIS. *(E.)* Swarbrick, E. T.; Loose, H.; Lennard-Jones, J. E. (St. Mark's Hosp., London, England). *Proc. R. Soc. Med.* 67(8):753-754, 1974.

A group of patients with active ulcerative colitis being treated with corticosteroid retention enemas (solution tablets of prednisolone-21-phosphate dissolved in tap water) was studied. Five percent by volume of barium suspension was added to the solution. A plain abdominal film was then taken to mark how far the enema traveled. This distance was then compared with the known extent of disease in each individual. Use of 50 ml, 100 ml, and 200 ml of fluid showed that any given volume came into contact with an unpredictable area of colon. Generally, 50 ml remained in the rectosigmoid, but even with volumes of up to 200 ml the whole colon was rarely covered. In general, increasing the volume by 50 ml over a few days resulted in an increasing area of the colon being treated, but this was not consistently the case. In studies on 10 patients using 100 ml for several days, the proximal limit reached by the enema was the same on each day in 5 patients. In 3 patients there were small variations in the distance traveled, and in 2 patients the enema did not travel as far because the disease was healing and solid stool could be detected on the X-ray of the colon which had previously been empty. Thus, the degree of penetration between different patients was unpredictable, but it appeared fairly constant within individuals with active disease. For topical corticosteroid therapy to be effective the steroid solution and the inflamed mucosa must come into contact. When the disease is confined to the distal colon and rectum, an enema volume of 100 ml is usually adequate. When the colitis is more extensive, the enema containing the 5% barium suspension should be administered to the maximum volume easily retained by the patient and the distance thus penetrated be compared with the extent of disease in that individual. Only in this manner can adequate individualized treatment be established.

PANCREAS

7919 COMPARISON OF STANDARD AND AUGMENTED SECRETIN TEST RESPONSES IN PATIENTS WITH AND WITHOUT PANCREATIC DISEASE: DELINEATION OF THE PANCREATIC TUBULAR CELL MASS AND ITS ALKALINE SECRETORY CAPACITY. *(E.)* Dreiling, D. A.; Greenstein, A. J.; Bordalo, O. (Mount Sinai Hosp., New York, N.Y.). *Am. J. Gastroenterol.* 61(6):433-442, 1974.

Secretory responses to standard secretin stimulation (1.0 U/kg iv.) and to augmented stimulation (4.0-5.0 U/kg iv.) were studied in 130 patients without pancreatic disease, 91 with chronic pancreatitis, 52 with pancreatic cancer, 83 with pancreatic hypersecretion, and in 9 patients following Duval resection (70-80%) of the pancreas. Gastric and duodenal secretions were collected for 80 min during both the standard and augmented tests. In subjects without pancreatic disease, quadrupling the secretin stimulus resulted in a 100% increase in the rate of flow and the rate of bicarbonate secretion, a 5% increase in mean bicarbonate concentration, and a 30% increase in amylase secretion. In patients with chronic pancreatitis, pancreatic cancer, and pancreatic hypersecretion, rates of secretory flow and bicarbonate secretion increased 40, 15, and 85% resp., following augmented secretin stimulation. Bicarbonate concentration remained fixed or decreased in patients with chronic pancreatitis but increased 10% in those with pancreatic cancer and pancreatic hypersecretion. Patients with pancreatic hypersecretion showed a 50% increase in amylase secretion response to augmented stimulation, whereas those with pancreatic cancer and chronic pancreatitis showed the same increase seen in the normal series. In 8 pancreatic resection patients, secretin response data were similar after standard and augmented stimulation, confirming the hypothesis of fixation of secretion and demonstrating the capacity of the pancreas to regenerate ductular and acinar tissue capable of delivering significant quantities of bicarbonate and enzyme to the duodenum. The results of sequential testing with standard and augmented stimuli suggest that a standard secretin test is sufficient for normal subjects. If low flow or low bicarbonate is encountered, the standard test should be immediately followed by an augmented test.

7920 ROLE OF SPLENIC ARTERIOGRAPHY IN EVALUATION OF MALIGNANT TUMORS IN THE BODY OF THE PANCREAS.

(E.) Suzuki, T.; Kitagawa, S.; Honjo, I. (Kyoto Univ. Med. Sch., Japan). *Surg. Gynecol. Obstet.* 139(4):509-513, 1974.

Selective arteriography, performed in 29 patients with carcinoma of the body of the pancreas which extended to the surrounding tissues beyond the border of the gland, was divided into 4 types according to the degree and pattern of tumor infiltration to the splenic artery: normal appearing, smooth tapering, rough tapering, and obstructing types. These divisions accounted for 3, 7, 13, and 6 patients, resp. The former 2 types were present in cases of cystadenocarcinoma (2), acinar cell carcinoma (1), nonfunctioning islet cell carcinoma (1), sarcoma (1), and carcinoid (1), as well as ductal cell carcinoma (4). All 19 of those with the latter 2 types had ductal cell carcinoma. Patients in the former group had metastases of the liver, those in the latter group had peritoneal dissemination. The longest average survival period (10.9 months) and highest percentage of resectability (100%) were in those patients with the normal appearing type, in whom the splenic artery showed no invasive signs by the tumor. The poorest prognosis, average 2.4 months survival time and 0% resectability, was in those patients with the obstructing type with the splenic artery completely interrupted by the lesion. In those with the smooth tapering and rough tapering types the prognosis was also poor, but removal of the main tumor in those with the smooth tapering type prolonged survival time. Hyperglycemia and severe lumber pain were frequent in those with the obstructing type. However, no significant differences in serum amylase, abdominal pain, or weight loss among each type was noted. Arteriography can help in the evaluation of malignant tumors of the body of the pancreas, a task for which only a few tools have yet been established.

7921 EXPERIENCE WITH ENDOSCOPIC RETROGRADE PANCREATICOGRAPHY.

(E.) Anacker, H.; Weiss, H. D.; Kramann, B.; Rupp, N. (Inst. Roentgenol. Diag., Tech. Univ., Munich, Germany). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(2):375-384, 1974.

Endoscopic retrograde pancreaticography was used for 650 examinations. Based on these observations an anatomical nomenclature of the pancreatic duct system was proposed. In the course of the normal evacuation of the pancreatic duct, 3 different phases were distinguished: contraction phase; evacuation phase; and resting phase. The average time for evacuation of the whole pancreatic duct system, after removal of the catheter from the papilla of Vater, took between 2 and 7 min. In papillary stenosis and in papillary spasm these phases were changed pathologically and the total evacuation time was prolonged. Malformation of the pancreas could only be visualized on retrograde pancreaticography if they communicated with the duct system. In chronic pancreatitis there were irregularities of the outline of the course of the duct with progress of the disease caused by ectasis, solitary or multiple stenoses, and deformities of the side ducts. Stones in the pancreatic main duct appeared as defects in the contrast medium filling. The special value of endoscopic retrograde pancreaticography lies in the diagnostic proof of pancreatic abscesses and pseudocysts shown by contrast medium extraductation. In cases of an abscess, there was a circumscribed contrast medium extraductation, usually 1-2 cm in size, sometimes with irregular contrast medium filling defects due to necrotic material or sequestra in the necrotic cavity. The diagnosis of abscess, as a space-occupying lesion, was confirmed by displacement of a larger duct. In pseudocyst there was a diffuse extraductation of contrast medium out of an autodigested or perforated duct, corresponding to the pathologic anatomic finding. The duct changes seen in pancreatic carcinoma were often similar to those of chronic pancreatitis. The normal appearance of the pancreatic main duct and side ducts between the tumor and papilla, and evaluation of all clinical and radiologic findings frequently allow the correct differential diagnosis.

7922 CARCINOMA OF THE PANCREAS. A PROGRAM FOR INCREASING SURVIVAL.

(E.) Humphrey, L. J.; Hartman, G. V. (Kansas Univ. Med. Ctr., Kansas City). *J. Kans. Med. Soc.* 75(9):281-282, 1974.

Immunotherapy combined with radiation therapy was used to treat 17 patients with incurable carcinoma of the pancreas without jaundice, ascites, or inanition. Most patients presented with jaundice which was relieved by a bypass procedure. Six patients received 4500-5000 rads to the pancreas over 4 1/2 to 5 weeks, followed immediately by 8 weeks of immunotherapy utilizing Vaccine I, prepared by mincing cancer tissue removed at surgery or autopsy, homogenizing the material, and freezing and thawing three times. At the conclusion of vaccine injections, these 6 patients underwent an exchange of white blood cells. The other 11 patients received 3000 rads during weeks 1, 2 and 3; Vaccine II during weeks 4, 5, 6 and 7; 2000 rads during weeks 8 and 9; and Vaccine II for weeks 10, 11, 12 and 13. No white blood cell exchange was performed on these 11 patients. To prepare Vaccine II, Vaccine I was centrifuged at 102,000 X g for 75 min. The supernatant was concentrated and frozen until ready for use. Both vaccines were administered intradermally and s.c. in either anterior thigh as 1 ml injections/week for a total of 8 injections. No untoward effects were noted. Of the first 6 patients, 2 died within 1 month of white blood cell exchange. The others survived an average of 18 months. In 2 of these a palpable pancreatic mass disappeared after completion of the combined therapy. Of the 11 patients receiving Vaccine II, 1 died 2 months after treatment of a pulmonary embolus; 6 died 2 to 5 months after treatment; the other 4 are alive at 5, 9, 9, and 10 months after therapy. As the known average survival time following bypass palliative treatment for carcinoma of the pancreas is 6.6 months, data from this study shows some improvement. A program for treatment of patients with carcinoma of the pancreas has been devised which includes: either resection or bypass procedure; 4000 to 5000 rads to the pancreas; immunotherapy consisting of Vaccine II injections for 4 to 8 weeks concluded by white blood cell exchange; and 500 mg 5-fluorouracil, p.o., beginning with radiation therapy and continuing weekly for an indefinite period.

7923 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN THE DIAGNOSIS OF PANCREATIC CANCER. EXPERIENCE WITH 54 CASES. *(E.)* Stadelmann, O.; Safrany, L.; Loffler, A.; Barna, L.; Miederer, S. E.; Papp, J.; Kaufer, C.; Sobbe, A. (Surg. Clin., Univ. Bonn, Germany). *Endoscopy* 6(2):84-93, 1974.

7924 CARCINOMA OF THE PANCREAS—EARLY DIAGNOSTIC PRESUMPTIVE SIGNS. *(E.)* Smith, E. B. (no affil.). *J. Natl. Med. Assoc.* 66(6):496-498, 1974.

PANCREAS

Pancreatitis

7925 LATENT ONSET OF CLINICAL PANCREATITIS IN CHILDREN RECEIVING L-ASPARAGINASE THERAPY. *(E.)* Weetman, R. M.; Baehner, R. L. (Indiana Univ. Sch. Med., Indianapolis). *Cancer* 34(3):780-785, 1974.

The pancreatic toxicity of L-asparaginase was studied in 43 children (26 boys and 17 girls) (48 trials of therapy) with either acute lymphocytic leukemia or acute undifferentiated leukemia. Some of the patients had advanced disease refractory to conventional oncotoxic therapy and others were being induced initially with vincristine, prednisone, and L-asparaginase in combination. The L-asparaginase dosage ranged from 3000 to 6000 IU/m^2 i.m. 3 times/week in patients manifesting L-asparaginase pancreatic toxicity (specific activity range, 225 to 275 IU/mg protein). Of the 43 children, 5 developed transient hyperglycemia or diabetes mellitus (11.6%), all of whom were also on steroid therapy which could have potentiated the diabetes. Pancreatitis secondary to L-asparaginase therapy has been reported to occur during administration of the drug. However, 4 of the 7 patients who developed pancreatitis secondary to L-asparaginase developed their disease 4 days to 10 weeks after therapy ceased. Of these 7 who developed pancreatitis, 5 were girls older than 9 yr of age, when serum estrogen and other female sex hormones begin to rise. Endogenous estrogens may prolong the half-life of the drug or enhance enzyme activity in young adolescent females, making them more susceptible to L-asparaginase toxicity. Serum amylase values were elevated in all patients who developed pancreatitis and urine amylase values were elevated in 4. It is suggested that L-asparaginase should be discontinued if an elevated serum or urine amylase value is found.

7926 X-RAY FINDINGS OF PANCREATIC CYSTS DIAGNOSED BY ENDOSCOPIC PANCREATOCHOLANGIOGRAPHY. *(E.)* Seifert, E.; St. Stender, H.; Safrany, L.; Lesch, P.; Luska, G.; Misaki, F. (Med. Sch., Hanover, Germany). *Endoscopy* 6(2):77-83, 1974.

During a 3-yr period, a total of 32 pancreatic cysts were diagnosed by endoscopic pancreatocholangiography with a fiberoptic duodenoscope, and the diagnosis was confirmed by subsequent surgery. Based on x-ray findings, signs characteristic or suspicious of pancreatic cysts are: 1) direct filling of the cyst cavity, 2) a filling defect in the pancreatic branches and parenchyma, 3) obstruction of the main pancreatic duct, either abrupt or tapering, 4) displacement and/or compression of the common bile duct. Cysts were found in the head of the pancreas in 17 cases and in the tail in 15 cases. Single cysts were more common than multiple ones. The finding of a pancreatic cyst, or of signs suspicious of a cyst, is an indication for surgery. Filled cysts without discharge into the main duct must be operated upon within 10 hr of endoscopy because of the greatly increased risk of infection resulting from the procedure.

7927 ENDOSCOPIC PANCREATOGRAPHY IN THE EVALUATION OF PATIENTS WITH SUSPECTED PANCREATIC PSEUDOCYSTS. *(E.)* Silvis, S. E.; Vennes, J. A.; Rohrmann, C. A. (Univ. Minnesota Med. Sch., Minneapolis). *Am. J. Gastroenterol.* 61(6):452-459, 1974.

Pancreatographic findings are presented for 16 patients with surgically proven pancreatic pseudocysts and 13 patients with suspected pancreatic pseudocysts. All patients with proven pseudocysts had abnormal studies. In 12 of the 16 the cyst was filled with contrast and in 2 additional patients the diagnosis of pseudocyst was suggested by deviation of the pancreatic and/or bile duct. In 1 patient with a mass deforming the upper gastrointestinal series, a pseudocyst was suggested by obstruction of the main duct. Of the 13 patients with suspected pancreatic pseudocysts, 9 had normal pancreatograms. Surgery on 3 patients revealed 2 true cysts, neither of which filled with contrast material, and 1 carcinoma of the pancreas. The remaining patient was thought to have pancreatic edema which resolved. Serial pancreatograms obtained in 2 patients who were followed without operation showed spontaneous regression of pseudocysts over a period of 1 1/2 yr and 2 1/2 months, resp. This study demonstrates that pseudocysts frequently communicate with the major pancreatic ducts and may spontaneously resolve. Endoscopic pancreatography appears to be of value in the exclusion of suspected cases as well as in the diagnosis and treatment of pseudocysts.

7928 SECONDARY GASTRIC MURAL ABNORMALITIES SIMULATING PRIMARY DISEASE IN ISOLATED CHRONIC LEFT SUBPHRENIC ABSCESS AND ISOLATED CHRONIC PANCREATITIS. *(E.)* Feinberg, S. B.; Tully, T. E. (Univ. Minnesota Hosp., Minneapolis). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(2):413-418, 1974.

Gastrointestinal studies performed on 10 cases of isolated chronic left subphrenic abscesses and roentgen examinations performed on 48 cases of isolated left upper quadrant chronic pancreatitis were reviewed for evidence of mural changes of the stomach. Gastrointestinal studies were strongly positive in 5 of the subphrenic abscess cases, were minimally to moderately positive in 4, and were normal in 1. The roentgen examinations in chronic pancreatitis cases included routine gastrointestinal contrast medium examinations (36 patients) and plain film abdominal roentgenography (12 patients), none of which showed unequivocal gastric wall thickening. Of 52 contrast medium studies performed on the 36 patients, 37 were positive and showed: striking mural thickening in the form of nodular or serpentine folds of the entire upper one-third to one half of the stomach (10); local hypertrophy of the portion of stomach in contact with the pancreatic bed or lateral left upper quadrant including the gutter (12); simple nonspecific rugal hypertrophy (1); and positive classical changes of pancreatitis such as widening and defacement of the duodenal loop, spasm of duodenitis, pseudocyst gastric displacement, pancreatic necrosis, and pancreatic calculi without gastric wall abnormalities (14). In the 5 severe subphrenic abscess cases, findings were more localized to cardia and fundus, the mucosa was not disrupted or ulcerated, the rugae were more nodular and the wall was more likely locally thickened in a circumferential fashion. The pars media was less involved and extended primarily no further than the upper third thereof. In the 10 severe pancreatitis cases gastric involvement was more extensive, but more prominent along the lesser curvature, posterior wall, and greater curvature aspect of the stomach even though the folds were less thickened and less abnormal in the cardia and fundus than in the pars media. The fold and mural patterns were less nodular and more longitudinally serpentine than in the isolated abscess cases. Based on these 15 pancreatitis and subphrenic abscess cases, differentiation between extensive chronic pancreatitis or subphrenic abscess induced gastric induration is possible and the site of origin of the extragastric inflammation is probably determinable.

7929 METHEMALBUMIN IN THE DIAGNOSIS OF ACUTE HEMORRHAGIC PANCREATITIS. *(E.)* Geokas, M. C.; Rinderknecht, H.; Walberg, C. B.; Weissman, R. (Sepulveda VA Hosp., Los Angeles, Calif.). *Ann. Intern. Med.* 81(4):483-486, 1974.

Serum, ascites fluid and pleural effusion levels of methemalbumin were studied in patients with acute edematous or hemorrhagic pancreatitis, and in patients with unrelated disease. The serum methemalbumin level ranged from 0.9-8.8 mg/100 ml in 17 alcoholic patients with acute hemorrhagic pancreatitis, and 1 with pancreatitis and acute cholecystitis. Ascites fluid in these patients (14 men and 4 women, aged 27-86 yr) contained 2.6-54 mg/100 ml methemalbumin. The level of methemalbumin in pleural effusions from 7 of the 18 ranged from 2-12 mg/100 ml. In 20 patients (10 women and 10 men, aged 21-64 yr) with acute edematous pancreatitis (including 10 alcoholics, 9 with gallstone pancreatitis, and 1 with acute pancreatitis of pregnancy), no methemalbumin was found in serum or ascites fluids tested throughout hospitalization. Daily test results revealed no methemalbumin in serum from 5 patients (aged 26-58 yr) with gastrointestinal bleeding and 2 patients (aged 48 and 54 yr) with intraabdominal hemorrhage. Early differentiation between acute edematous and hemorrhagic pancreatitis is essential for treatment and good prognosis. By testing serum and ascites fluid or pleural effusions for methemalbumin, the 2 types of pancreatitis can be distinguished early in the course of the disease. The detection of methemalbumin in serum and enzyme studies compatible with acute pancreatic inflammation should be considered virtually pathognomonic of the hemorrhagic form.

LIVER AND BILIARY TRACT

7937 LIVER HAMARTOMAS IN PATIENTS ON ORAL CONTRACEPTIVES. *(E.)* O'Sullivan, J. P.; Wilding, R. P. (St. George's Hosp., London, England). *Br. Med. J.* 3(5922):7-10, 1974.

Benign liver cell tumors occurred in 3 women who had been taking oral contraceptives (lynoestrenol-mestranol, ethynodiol-mestranol, and norethindrone-mestranol) for at least 4 yr. One patient presented with vague gastrointestinal symptoms, 1 with a symptomless abdominal lump, and in 1 the liver mass was found incidentally at cholecystectomy. Celiac angiography performed in 2 patients showed an abnormal vasculature. In these 2 patients the lesion was at the tip of the right lobe and local removal was performed. In the 3rd patient the nodule was in the medial part of the left lobe and only frozen-section biopsy was performed. In all cases dilated endothelium-lined vascular channels were present and the remainder of the liver was normal. The lesions in these patients are best described as hamartomatous nodules rather than benign liver cell adenomas. This diagnosis must be considered in any patient with clinical features of bleeding into the peritoneal cavity, particularly if a mass is palpable in the upper abdomen. Both liver scan and celiac arteriography are helpful in diagnosis; needle biopsy is contraindicated due to the risk of hemorrhage. In view of the high death rate from hemorrhage in previously reported cases, these hamartomas should be removed. In elective cases, the choice is between local removal and a formal lobectomy. Treatment in emergency cases is aimed at controlling blood loss with liver resection. Practioners should exclude the presence of an epigrastic mass in a patient before prescribing oral contraceptives and should consider hepatic hamartoma as a possible cause of hemoperitoneum in women on the pill.

7938 PRIMARY NON-DIFFERENTIATED SARCOMA OF THE LIVER. CASE REPORT AND REVIEW OF THE LITERATURE. *(E.)* Mattila, S.; Keskitalo, E.; Makinen, J. (Dept. Thoracic Surg., Univ. Helsinki, Finland). *Acta Chir. Scand.* 140(4):303-307, 1974.

A case of primary nondifferentiated sarcoma of the liver occurred in a 68-yr-old woman. Serum bilirubin was 6.0 mg/100 ml, and alkaline phosphatase, 89 U/liter. Symptoms included pain, caused by a right upper quadrant mass, which radiated to the right shoulder. Acute rupture and bleeding of the tumor led to emergency operation for suspected acute peritonitis. The tumor was found to have replaced the whole right lobe of the liver and infiltrated the medial segment of the left lobe. No evidence of metastasis was found at operation. To stop the bleeding it was necessary to resect the whole right hepatic lobe and the medial segment of the left lobe. After operation hypokalemia, acidosis, hyperglycemia, and atrial fibrillation occurred, all of which were successfully treated. The patient recovered uneventfully from surgery and showed good regenerative capacity of the liver. However, death occurred 5 months later due to metastases of the tumor. At autopsy, the liver was free from tumor growth, but there were metastases in the abdominal and pleural cavities. The tumor was histologically classified as a malignant mesenchymal sarcoma composed mainly of spindle cells. There were arrangements of the cells into cords and whorls and larger cells with abundant cytoplasm. The lack of detectable cross-striation prevented a closer classification of the tumor. Resection of the tumor combined with preoperative radiotherapy is the treatment of choice in such cases.

7939 PRIMARY LIVER CANCER, ALPHA$_1$ FETOPROTEIN AND HEPATITIS B ANTIGEN IN PAPUA NEW GUINEA. *(E.)* Woodfield, D. G.; Endo, Y.; Matsuhashi, T. (Red Cross Blood Transfusion Service, Boroko, Papua New Guinea). *Aust. NZ J. Med.* 4(1):3-7, 1974.

Conventional and radioimmunoassay techniques used for the detection of α_1-fetoprotein and hepatitis B antigen (HBAg) and antibody in sera from 72 Papua New Guinean patients with primary liver cell cancer are described. The male:female ratio of the study group was 4.5:1; mean age of males was 33.1 yr, of females, 34.2 yr. Of 51 patients with histologically diagnosed hepatic cell carcinomas, 48 (94%) had sera positive for α_1-fetoprotein detected by double immunodiffusion. Of the 3 samples negative for α_1-fetoprotein by this test, 2 were positive by radioimmunoassay and 1 was negative. Of 72 patients with histologically diagnosed tumors or α_1-fetoprotein positive sera, 19 (29%) were positive for HBAg by immunoelectroosmophoresis. Using immuno-adherence hemagglutination assay, 55 (76%) of these patients were positive for HBAg. Of the 17 negative HBAg samples, 4 were positive by radioimmunoassay. Of the 72 samples tested, two specimens (2.8%) contained HB antibody by the passive hemagglutination technique. Thus the double immunodiffusion technique was adequate for the detection of α_1-fetoprotein in most primary hepatic cancers in Papua New Guinea. The fact that the incidence of α_1-fetoprotein production in experimentally produced liver cell cancers in animals varies with the carcinogenic agent used suggests a single etiological factor may be involved in liver cancer in Papua New Guinea, possible naturally occurring hepatotoxins and fungal contaminants of food, mainly aflatoxins, known to be hepatocarcinogenic in animals. The reason for the high frequency of HBAg in liver cancer is not known. The possibility that disturbed immunity may be involved is strengthened by the finding of HB antibody in only 2.8% of the patients with liver cell carcinoma, which may indicate an immune reaction absorbing any antibody produced, and removing antigen from the sera.

7940 EXPERIMENTAL AND CLINICAL STUDIES ON THE INCREASE IN SERUM γ-GLUTAMYL TRANSPEPTIDASE ACTIVITY IN HEPATOBILIARY DISEASE. *(Ger.)*

Thiele, K. G.; Holmes, A. W.; Mattenheimer, H. (Med. Clin., Univ. Cologne, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:925-927, 1973.

Serum and liver γ-glutamyltranspeptidase (GGTP) activities were determined in 8 marmosets 24 hr to 6 months after ligation and sectioning of the common bile duct and cholecystectomy under phencyclidine anesthesia. Controls consisted of 4 sham-operated animals and 4 anesthetized animals. Progressive increases occurred in GGTP activity in the livers of both operated and sham-operated controls. Although mean values were lower in sham-operated animals than in animals with ligated bile ducts 120 hr after surgery, the difference was not significant. Alkaline phosphatase activities in the liver followed a similar pattern, and no significant difference was found between operated and sham-operated animals. No appreciable change in glutamate-oxalate transaminase and glutamate dehydrogenase activities occurred in the liver, while mean glutamate-pyruvate activities decreased 59% after 120 hr. Serum GGTP activities increased 64-fold in operated animals and only 5-fold in sham-operated animals 120 hr after surgery. Both liver and serum GGTP activities had decreased significantly 5 weeks after surgery. Acute carbon tetrachloride (CCl_4) intoxication (1.25 ml/kg) caused a 114% increase in liver GGTP activity after 12 hr and a 267% increase after 36 hr. Septal fibrosis and localized steatosis, induced in 4 animals by repeated i.p. injection of CCl_4 over an 8-week period, was accompanied by a 4-fold increase in GGTP activity in the liver and a 2.8-fold increase in serum. Of 12 marmosets with infectious hepatitis, only 5 showed increases in serum GGTP activities. These values reached values 6 times the initial levels an average of 8 weeks after inoculation. Thus, in contrast to other findings in the literature, increases in GGTP and alkaline phosphatase in the liver are not specific for cholestasis. When GGTP activity was measured in serum and liver homogenates from 54 patients with various liver diseases, alcoholics with fatty liver had the highest GGTP activities in the liver while the highest serum activities were found in patients with extra- or intrahepatic cholestasis. The liver/serum concentration gradient was significantly smaller in these patients than in those with other liver diseases. Except for patients with cholestasis, a significant correlation was found between GGTP activities in the liver and serum. Therefore, it is possible that GGTP can pass directly from damaged liver cells into the blood. These findings indicate that 2 mechanisms are involved in the increase in GGTP activity which occurs in the serum in hepatobiliary disease: (1) an increase in enzyme synthesis in the liver during which the permeability of cell membranes remains the same or increases and (2) regurgitation of GGTP which cannot be excreted in the bile when bile flow is obstructed.

7941 HEPATIC ABSCESS: CHANGES IN CLINICAL, BACTERIOLOGIC AND THERAPEUTIC ASPECTS. *(E.)*

Rubin, R. H.; Swartz, M. N.; Malt, R. (Massachusetts Gen. Hosp., Boston). *Am. J. Med.* 57(4): 601-610, 1974.

Clinical, bacteriologic, and therapeutic aspects of 53 patients with hepatic abscesses seen from 1961 to 1973, are reviewed. Total mortality was 63%. Patients over 50 yr of age constituted the greatest number of cases (38) and mortality among them was 79%. Fifty abscesses were pyogenic and 3 amebic in etiology. Macroscopic abscesses were present in 35 cases and microscopic in 18. Macroscopic pyogenic abscesses were most commonly caused by biliary tract infection (11 cases), direct extension from contiguous sites of infection (8 cases), and nonpenetrating trauma usually the result of an auto-accident (5 cases). The micro abscesses were found to be caused by biliary tract infection (9 cases), systemic bacteremia (8 cases) and pylephlebitis (1 case). Hepatic scintiscan and abdominal angiography provided positive findings in all cases where the abscess exceeded 1 cm in diameter. Bacteria of bowel origin (especially *E. coli*) were the common etiologic agents. In children with bacteremia, *Staph. aureus* is predominantly implicated. Effective therapy relies in prolonged administration of antibiotics and aggressive surgical drainage.

7942 SOLITARY NEONATAL HEPATIC ABSCESS. *(E.)*

Kandall, S. R.; Johnson, A. B.; Gartner, L. M. (Albert Einstein Coll. Med., Bronx, N.Y.). *J. Pediatr.* 85(4):567-569, 1974.

A solitary hepatic abscess was found at postmortem examination in a female neonate who died at 25 days of age. The infant was delivered by cesarean section at 35 weeks of a normal gestation after signs of fetal distress developed during labor. The infant was severely depressed at birth and weighed 2500 g. An umbilical catheter was initially placed without rigid aseptic conditions. The mother had undergone amniocentesis several weeks previously. Chest x-ray at 4 hr of age showed elevation of the right hemidiaphragm which persisted throughout the hospital course. The baby was managed by ventilatory assistance, regulation of arterial blood gases, maintenance of blood pressure, systemic antibiotics, and hyperalimentation for the last 15 days of life. On day 25, the infant developed abdominal distension and bradycardia and had a cardiac arrest. Urine and blood cultures were consistently negative until the final day of life when a blood culture grew *Enterobacter liquifaciens*. Liver function tests were normal. Autopsy revealed 200 ml clear peritoneal fluid and elevation of the right hemidiaphragm with purulent material between the dome of the liver and the right diaphragm and an abscess cavity within the right lobe of the liver. Culture of the hepatic abscess showed many coliform bacteria. The findings suggested that the hepatic abscess was probably present at birth. Recognition of the association between hepatic abscess and congenital diaphragmatic elevation might have led to surgical intervention and increased the infant's chance of survival. A liver scan with technetium-sulfur colloid should be performed when neonatal liver abscess is suspected. Clarification between a vascular space-occupying mass and an abscess could then be made by dynamic nuclide angiography with sodium pertechnetate.

7943 LIVER ENZYMES AND PATHOLOGY IN HODGKIN'S DISEASE. *(E.)* Belliveau, R. E.; Wiernik, P. H.; Abt, A. B. (U.S. Public Hlth. Service Hosp., Baltimore, Md.). *Cancer* 34(2):300-305, 1974. 305, 1974.

Liver pathology and the levels of serum enzymes of presumed hepatic origin (alkaline phosphatase (AP), γ-glutamyl transpeptidase (γ-GT), SGOT, and 5'-nucleotidase (5'N)) were correlated in 67 patients with Hodgkin's disease to determine the degree to which the serum measurements reflect hepatic involvement in the disease. Forty-seven of the patients were untreated (8 Stage I, 18 Stage II, 14 Stage III, and 7 Stage IV), 20 having been previously treated (2 Stage I, 4 Stage II, 5 Stage III, and 9 Stage IV). Eleven patients had hepatic lesions diagnostic of Hodgkin's disease, 3 had epithelioid cell granulomata, and 31 had nonspecific abnormalities. Serum AP levels were elevated in patients with liver biopsies demonstrating Hodgkin's disease, granulomata, cholestasis, and hepatitis, a slightly higher mean value occurring in patients with hepatic Hodgkin's disease. Patients with advanced Hodgkin's disease tended to have higher serum AP levels than patients with localized disease whether or not Hodgkin's disease of the liver was demonstrated. Serum γ-GT levels were 2- to 3-fold higher in patients with granulomata, cholestasis, and hepatitis than in those with Hodgkin's disease. SGOT and serum 5'N levels were highest in patients with hepatitis and cholestasis. The data indicate that liver biopsy is the only definitive method for determining hepatic involvement in Hodgkin's disease.

7944 HEPATIC PATHOLOGY ASSOCIATED WITH HODGKIN'S DISEASE. *(E.)* Abt, A. B.; Kirschner, R. B.; Belliveau, R. E.; O'Connell, M. J.; Sklansky, B. D.; Greene, W. H.; Wiernik, P. H. (U.S. Public Hlth. Service Hosp., Baltimore, Md.). *Cancer* 33(6):1564-1571, 1974.

Liver biopsies obtained from 103 untreated and 25 previously treated patients during staging laparotomy for Hodgkin's disease were reviewed. Wedge biopsies from at least one hepatic lobe were obtained from 70 patients. The treated patients had received radiation and/or chemotherapy. No significant differences were noted between the two groups in terms of the incidence of Hodgkin's disease, epithelioid cell granulomata, or nonspecific inflammation. The treated patients showed a nonsignificant increase in fatty infiltration and hemosiderosis. Elevated serum alkaline phosphatase levels were associated with nonspecific lesions, Hodgkin's disease, and normal biopsies. There was no apparent relation between different nonspecific abnormalities in the same biopsy, or between the nonspecific lesions and hepatic Hodgkin's disease. Eleven patients had splenic granulomata, and 9 of 10 patients with epithelioid cell granulomata of the liver had similar splenic lesions. Hepatitis-associated antigen was found in 5 patients: 2 untreated patients with nonspecific portal inflammation, 1 untreated patient with Hodgkin's disease, 1 treated patient with chronic active hepatitis, and 1 treated patient with a focal fatty infiltration; 3 of these patients also demonstrated hemosiderosis. The needle biopsies revealed no lesions not demonstrated by the wedge biopsies. Careful examination of the liver surface during laparotomy is important.

7945 HEPATIC HEXOKINASE ISOZYME IN LIVER DISEASES. *(E.)* Ueda, M.; Taketa, K.; Shimamura, J.; Kosaka, K. (Okayama Univ. Med. Sch., Japan). *Clin. Chim. Acta* 53(3):381-383, 1974.

Activities of hexokinase isozymes were determined in liver supernatants prepared from needle-biopsy specimens from 4 patients with liver diseases (acute hepatitis, chronic hepatitis, postnecrotic cirrhosis, and hepatocellular carcinoma, resp.) and from 1 patient with no histological evidence of specific liver disease and with normal glucose tolerance. Hexokinase (glucokinase) activities were determined spectrophotometrically at 0.5 and 100 mM glucose concentrations. Enzyme extracts were applied stepwise in total amounts of 8 µl each/12 mm. After electrophoresis on a cellulose acetate gel membrane, enzyme activity was visualized with 0.5 and 100 mM glucose as substrate; and the strip developed with 0.5 mM glucose was analyzed by densitometry to estimate the relative intensities of low K_m hexokinase bands. The activities of hexokinases I, II, and III were calculated from the relative intensities of these bands and from total activity of the original extract. The results suggest that the pattern of hepatic hexokinase isozymes may differ significantly in various stages of liver disease. There was a marked increase in Type III hexokinase in acute hepatitis and a gradual increase in Type I hexokinase with progression of disease from chronic hepatitis to cirrhosis and possibly to primary hepatoma. Type II hexokinase was absent in normal liver, chronic hepatitis, and hepatocellular carcinoma. Examination of hepatic hexokinase isozymes by the present method may be of value in establishing differential diagnosis as well as in elucidating the pathophysiology of liver diseases.

7946 ABNORMAL LIVER SCANS IN PATIENTS WITH ALPHA$_1$-ANTITRYPSIN DEFICIENCY. *(E.)* Yun Ryo, U.; Moses, D. C.; Milam, W. F. (Univ. Michigan Med. Ctr., Ann Arbor). *J. Nucl. Biol. Med.* 18(2):39-43, 1974.

Abnormal liver-spleen scans were obtained in 2 men (47 and 52 yr old) with emphysema and heterozygous α_1-antitrypsin deficiency. The first patient also had hyperthyroidism and abnormal liver function tests (SGOT, SGPT, LDH alkaline phosphatase, and serum albumin) and presented with progressive shortness of breath and weight loss. His liver-spleen scan showed nonhomogeneous and decreased uptake into the liver with increased spleen uptake, splenomegaly and increased bone marrow uptake. Liver biopsy showed cirrhosis. Many hepatocytes contained periodic acid-Schiff-positive cytoplasmic inclusion bodies characteristic of those found in patients with α_1-antitrypsin deficiency. The second patient also presented with progressive shortness of breath. He had slight hepatomegaly but liver function tests were normal. Liver-spleen scan showed patchy uptake and hepatomegaly. No liver biopsy was obtained. These cases illustrate a possible role for liver scanning in screening and following α_1-antitrypsin deficiency of liver disease.

7947 AN ISOENZYME OF 5'-NUCLEOTIDE PHOSPHODIESTERASE AND α-FETOPROTEIN IN HUMAN HEPATIC CANCER PATIENT SERA. *(E.)* Tsou, K. C.; McCoy, M. G.; Lo, K. W. (Sch. Med., Univ. Pennsylvania, Philadelphia). *Cancer Res.* 34(10):2459-2463, 1974.

Sera from 43 patients with primary hepatoma and from 55 patients with other cancers metastatic to liver were studied for the presence of a 5'-nucleotide phosphodiesterase (5'-NPDase) isoenzyme (band V, quickly migrating on polyacrylamide gels) and α-fetoprotein. Results indicated that the serum 5'-NPDase assay is a more reliable and sensitive test for primary hepatoma and metastatic liver cancer than is the serum α-fetoprotein assay by immunodiffusion. The 5'-NPDase isoenzyme was detected in 38 of the 43 patients with primary hepatoma and in 44 of the 55 patients with metastatic liver disease. α-Fetoprotein, by contrast, was detected in only 6 of the hepatoma patients by immunodiffusion and in another 6 of the 18 initially negative sera by counterimmunoelectrophoresis. Blocking studies using immunodiffusion showed that isoenzyme positive, α-fetoprotein-negative sera did not contain any component that would block or interfere with the reaction of α-fetoprotein with anti-α-fetoprotein. 5'-NPDase and α-fetoprotein had different mobilities on polyacrylamide gel electrophoresis. Trypsinization caused formation of a 5'-NPDase isoenzyme in band V position in normal and cord sera and an increased intensity in hepatoma serum, while removing or decreasing intensity of bands II, III and IV for all sera. Trypsinization of cord serum resulted in degradation of α-fetoprotein.

7948 METHIONINE ADENOSYLTRANSFERASE DEFICIENCY: NEW ENZYMATIC DEFECT ASSOCIATED WITH HYPERMETHIONINEMIA. *(E.)* Gaull, G. E.; Tallan, H. H. (N.Y. State Inst. Basic Res. Mental Retardation, Staten Island). *Science* 186(4158):59-60, 1974.

A specific deficiency of methionine adenosyltransferase has been demonstrated in extracts of liver from an infant with hypermethioninemia. The newborn, who was identified through a mass screening survey, had a plasma methionine level of 128 μM/100 ml, over 30 times the normal value. There was no homocystinemia, hypocystinemia, or cystathioninuria. The child has remained apparently normal to the age of 1 yr although electron micrographs of liver tissue obtained by percutaneous biopsy have shown breaks in the outer membranes of the mitochondria and hyperplasia of the smooth endoplasmic reticulum. Assays of liver extracts showed a specific methionine adenosyltransferase deficiency (range below that of a 2nd trimester fetus); activities of enzymes of the transsulfuration and remethylation pathways were normal. These findings collectively suggest that the defect is due to a genetic mutation rather than to a delay in enzymatic maturation or to an acquired disease.

7949 XERODERMA PIGMENTOSUM WITH LIVER INVOLVEMENT. *(E.)* Dupuy, J. M.; Lafforet, D.; Rachman, F. (INSERM, Parrot Hosp., Bicetre, France). *Helv. Paediatr. Acta* 29(3):213-219, 1974.

Cell viability following UV irradiation (2537Å, incident dose 8 erg/mm^2/sec) was assessed *in vitro* by the trypan blue exclusion test for peripheral lymphocytes from a 10-yr-old girl with xeroderma pigmentosum. The patient manifested liver involvement with hepatosplenomegaly, abnormal liver function tests, cholestasis with portal hypertension and deafness. Viability of control cells decreased slowly with increasing UV dosage: viability after exposure to 300 erg/mm^2 was 50% on day 5. In contrast, the survival fraction of the patient's cells decreased sharply with irradiation and the curve at 30 erg/mm^2 of UV was similar to that of control cells exposed to 300 erg/mm^2. Measurement of DNA synthesis by autoradiography following labeling with ^{3}H-thymidine showed similar rates for skin fibroblasts, hepatocytes and lymphocytes of normal donors and the xeroderma pigmentosum patient; after irradiation, there was a marked increase in average grain count of normal donor cells. There was no significant difference in average grain count between unirradiated and irradiated cells from the xeroderma pigmentosum patient, suggesting that xeroderma pigmentosum cells from liver, skin and lymphocytes are unable to repair DNA after UV irradiation.

7950 EFFECT OF DIPHENYLHYDANTOIN ON HEPATIC DRUG HYDROXYLATION. *(E.)* Petruch, F.; Schuppel, R. V. A.; Steinhilber, G. (Neurol. Clin., Univ. Tubingen, Germany). *Eur. J. Clin. Pharmacol.* 7(4):281-285, 1974.

The metabolic disposition of antipyrine (14 mg/kg p.o.) was examined in 8 male epileptics before and after 2.5-6 months of treatment with diphenylhydantoin (DPH, 300 mg/day). The average half-life of antipyrine fell from 10.0 ± 3.4 hr before treatment to 6.1 ± 1.6 hr after treatment. The amount of unchanged antipyrine excreted in urine decreased from 28.5 ± 12.1 mg/24 hr before treatment (2.8% of the dose administered) to 18.1 ± 10.2 mg/24 hr after treatment (1.8% of the dose). Similar results were obtained when the data were calculated on the basis of creatinine excretion. The amount of 4-OH-antipyrine excreted in urine increased from 185 ± 39 mg/24 hr before therapy (18% of the dose) to 300 ± 95 mg/24 hr after treatment with DPH (29% of the dose). In an additional epileptic patient who had Meulengracht's disease, the half-life of antipyrine decreased from 20.7 to 6.6 hr after 22 days treatment with DPH (300 mg/day); during the same time, the serum bilirubin concentration fell from 2.6 to 1.0 mg/100 ml. The results indicate that DPH enhances the activity of hepatic drug microsomal hydroxylating systems.

7951 VENTRAL PORTAL VEIN. *(E.)* Harell, G. (Stanford Univ. Sch. Med., Calif.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 121(2):369-373, 1974.

In 3 of the 10 basic variations seen in the human hepatic arterial blood supply, the portal vein runs ventral or in front of an aberrant right hepatic artery; in such instances the portal vein is termed a ventral portal vein. In 1 of these 3 variations (Type X variant), an aberrant right hepatic artery arises from the celiac axis independently of the common hepatic and courses dorsally or crosses behind the more ventrally positioned portal vein. In the other two (Types VII and VIIIA), an aberrant right hepatic artery arises from the superior mesenteric artery, proceeds upwards, and crosses behind a more ventrally located portal vein. Three cases involving these variations are discussed. In the case of a 59-yr-old woman, an aberrant right hepatic artery arose from either a short common hepatic artery or the celiac trunk and the portal vein probably crossed ventral to the aberrant right hepatic artery. Because of bleeding, the patient underwent splenectomy, a spleno-renal shunt being performed rather than a portacaval shunt. Had the latter been attempted, difficulty might have been encountered in bringing the ventral portal vein posteriorly. In the second case, a 62-yr-old woman had a visceral carcinoma involving an aberrant (Type X) right hepatic artery at the point where it crossed behind the portal vein; the ventral position of the portal vein in relation to the aberrant right hepatic artery suggested an anatomic basis for the lack of portal vein involvement. In a 55-yr-old with a Type X variant, the common hepatic artery and the origin of the ventral portal vein were both involved by a pancreatic carcinoma. The neoplasm also involved the origin of the aberrant right hepatic artery but spared the artery where it crossed behind the ventral portal vein. Awareness of the existence of a ventral portal vein may help in planning shunt surgery for portal hypertension.

7952 CHOLESTEROL ESTER STORAGE DISEASE: RADIOLOGICAL FEATURES. *(E.)* Carter, A. R.; France, N. E.; Lewis, B. W.; Shaw, D. G. (Queen Elizabeth Hosp. Children, London, England). *Pediatr. Radiol.* 2(2):135-136, 1974.

The rare condition of cholesterol ester storage disease was diagnosed in a 5-yr-old girl who developed hepatomegaly at the age of 3 yr and 8 months. She remained well until 5 yr of age when she also developed splenomegaly and an elevated serum cholestrol (312 mg%). X-ray of the abdomen showed extensive small areas of calcification scattered throughout the liver and a few small areas of calcification in the spleen. Serological tests were negative; serum, copper and iron were normal; and investigation of white blood cell enzymes ruled out glycogen storage disease. Open liver biopsy showed well-defined biliary cirrhosis with a large amount of lipid accumulation in hepatocytes and Kupffer cells. Biochemical analysis showed liver cholesterol ester levels about 200 times normal and slightly increased liver cholesterol and triglycerides. The basic metabolic defect in cholesterol ester storage disease is unknown. Of 5 reported cases, only one has died, of unrelated disease, suggesting a favorable prognosis.

7953 HEPATITIS-B ANTIGEN AND CIRRHOSIS IN BANTU PATIENTS WITH PRIMARY LIVER CANCER. *(E.)* Kew, M. C.; Geddes, E. W.; Macnab, G. M.; Bersohn, I. (Dept. Med., Univ. Witwaterswand, Johannesburg, South Africa). *Cancer* 34(3):539-541, 1974.

Hepatitis-B antigen (HBAg) was found in the serum of 30 of 75 (40%) Bantu patients with primary liver cancer, but in only 7% of 18,377 apparently healthy rural Bantu, confirming an association between this tumor and persistence of the hepatitis-B virus. No relation could be demonstrated between hepatitis-B antigenemia and α-fetoprotein, which was present in 77% of the patients. HBAg was not more common in the younger patients. In 60% of the patients, primary liver cancer coexisted with macronodular (postnecrotic) cirrhosis. HBAg was found in 45.6% of the patients with cirrhosis, but also in 31% of those without, an insignificant difference. These findings may indicate that persistence of the hepatitis-B virus is the cause or result of primary liver cancer, or that some immunologic defect is responsible for both. If the former, the virus must be directly oncogenic, in addition to having the potential to induce neoplasia indirectly *via* chronic parenchymal liver disease.

7954 ANGIOGRAPHY OF THE LIVER AND SPLEEN IN HODGKIN'S DISEASE. *(E.)* Jonsson, K.; Lunderquist, A. (Univ. Hosp., Lund, Sweden). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 121(4):789-792, 1974.

Angiography of the liver and spleen was performed in 18 patients with histologically proven Hodgkin's disease and the results were correlated with the findings at staging laparotomy, which included wedge biopsy of the liver and splenectomy. At angiography, nonspecific filling defects and dislocation of intrahepatic arteries were found in 1 patient with lymphoma in the liver. A 2nd patient with similar defects on angiography proved to have a smooth liver at laparotomy. Similar filling defects in the spleen are nonspecific and may occur in both involved and uninvolved cases. No specific angiographic pattern was seen in cases with epithelioid cell granulomas in the liver or spleen. An enlarged liver or spleen demonstrated either by palpation or by angiography is no proof of involvement and, at times, an apparently normal liver or spleen may actually be diseased. Thus, laparotomy remains the only reliable method of documenting organ involvement in lymphoma.

7955 A CLINICOPATHOLOGICAL REVIEW OF 100 CASES OF PRIMARY MALIGNANT TUMOURS OF THE LIVER.

(E.) MacSween, R. N. M. (Western Infirm., Glasgow, Scotland). *J. Clin. Pathol.* 27(8):669-682, 1974.

One hundred cases of primary malignant tumor of the liver coming to necropsy in the period 1900-1969 have been reviewed. The overall tumor incidence was 0.46% of all necropsies. The overall tumor incidence in hepatic cirrhosis was 12.3%, but the corresponding male and female incidences were 17.5 and 4.4%, resp. There was no significantly increased tumor incidence in hemochromatosis. An increasing incidence of primary malignant tumors of the liver has been noted since 1940 and appears to be due to a corresponding increase in incidence of hepatic cirrhosis (64% in this study). Hepatocellular carcinomas outnumbered cholangiocarcinomas by 8 to 1, were more common in males than females (6 to 1), and in 77% of cases occurred in cirrhotic livers. Tumors supervened as a complication of macronodular or predominantly macronodular cirrhotic patterns and were seen in 41 of 49 patients with this picture.

7956 ULTRASTRUCTURAL CHANGES IN LIVERS OF TWO PATIENTS WITH HYPERVITAMINOSIS A.

(E.) Hruban, Z.; Russell, R. M.; Boyer, J. L.; Glagov, S.; Bagheri, S. A. (Dept. Pathol., Univ. Chicago, Ill.). *Am. J. Pathol.* 76(3):451-468, 1974.

Liver tissue obtained by percutaneous biopsy of 2 patients (1 man and 1 woman, aged 63 yr and 54 yr, resp.) with hypervitaminosis A was studied by light and electron microscopy. Clinical manifestations in both patients included dry skin, hair loss, hepatosplenomegaly and ascites. Both had ingested excessive amounts of vitamin A for 5 to 8 yr. Direct vitamin A assays in liver biopsy specimens were 1,700 and 2,200 μg/g liver, as compared to controls of 100-130 μg/g. The principal distinctive ultrastructural changes observed were perisinusoidal fibrosis and massive accumulation of lipid-storing cells (Ito cells). The fibrosis consisted of a network of basement membranes with numerous bundles of collagen and reticulum fibrils. This network contained numerous Ito cells, and moderate numbers of lymphocytes, macrophoges and other mesenchymal cells. Impairment of blood flow by perisinusoidal fibrosis probably resulted in the secondary alterations in hepatocytes which included cellular atrophy and formation of cytoplasmic bullae.

7957 IMMUNOHISTOCHEMISTRY OF LIVER IN ALPHA$_1$-ANTITRYPSIN DEFICIENCY: A COMPARATIVE STUDY.

(E.) Palmer, P. E.; De Lellis, R. A.; Wolfe, H. J. (Tufts Univ. Sch. Med., Boston, Mass.). *Am. J. Clin. Pathol.* 62(3):350-354, 1974.

A retrospective light microscopic study was performed on liver tissue obtained at autopsy from 3 adults with α_1-antitrypsin deficiency and from 8 additional patients with a variety of hepatic diseases. Immunofluorescent and immunoperoxidase methods for the identification of α_1-antitrypsin-positive granules in liver cells were compared. In formalin-fixed frozen sections, specific intracellular globule staining was demonstrated in the deficiency state with all technics. While immunofluorescent methods failed to stain the globules in formalin-fixed, paraffin-embedded tissues, immunoperoxidase technics gave consistently positive and reproducible results. The immunoperoxidase technic utilizing an unlabeled antibody bridge was found to be better for demonstrating α_1-antitrypsin deposits in paraffin-embedded tissue specimens. The ability to detect α_1-antitrypsin deposits by the immunoperoxidase method enables retrospective analysis of paraffin-embedded tissues. The technique may also be applicable to ultrastructural analysis.

7958 THE SIGNIFICANCE OF LIPOPROTEIN X AND SERUM CHOLINESTERASE IN THE PREOPERATIVE DIAGNOSIS OF OBSTRUCTIVE JAUNDICE.

(Ger.) Prexl, H. J.; Petek, W. (Surg. Clin., Univ. Graz, Austria). *Chirurg* 44(7):310-313, 1973.

Cholinesterase activities were determined and lipoprotein-X (LP-X) concentrations measured by immunoelectrophoresis on sera from 178 patients who were scheduled to undergo biliary surgery. These included 33 patients who were suspected of having obstructive jaundice. The test for LP-X was negative in all of the 145 patients without jaundice, while LP-X concentrations of 5-46 mg/100 ml were found in 27 of the 33 jaundiced patients. At surgery, all of the patients who were LP-X-positive had extrahepatic biliary obstruction due to calculi or tumors. The 6 patients who were LP-X-negative all had parenchymal liver damage. Most LP-X-negative patients with moderately increased serum transaminase activities, alkaline phosphatase activities of up to 200 mU/ml, and serum cholinesterase activities of 1000-1600 mU/ml had cirrhosis. LP-X-positive patients were classified into 2 groups on the basis of their serum cholinesterase activities. Those with moderately elevated transaminase activities, greatly increased alkaline phosphatase values, and normal or slightly subnormal serum cholinesterase levels (1700 mU/ml) generally did not have tumors. A large decrease in the serum cholinesterase level (below 1200 mU/ml) was either a manifestation of a benign biliary obstruction which had caused secondary parenchymal liver damage or, more frequently, malignant tumors of the biliary tract or pancreas which caused extrahepatic biliary obstruction.

7959 METABOLIC CHANGES AFTER HEPATIC DEARTERIALIZATION IN MAN. *(E.)* Nagasue, N. (Saiseikai Yahata Hosp., Yahata, Kitakyushu, Japan). *Jap. J. Surg.* 3(3):173-183, 1973.

Diffuse liver cancer in 5 male patients was treated by hepatic dearterialization. Metabolic changes thus induced were examined for 3 weeks postoperatively. The transient rise of blood glucose level on the 1st postoperative day was more pronounced than in usual laparotomy cases, indicating glucose intolerance. Serum phospholipids and total cholesterol values decreased markedly, reaching the lowest level in the 2nd week. There was no definite tendency in the changes in serum triglycerides and free fatty acids levels. Serum albumin decreased markedly during the first 2 weeks in all cases, indicating impaired albumin synthesis. Serum α_2-globulin levels, however, showed a rapid increase during the same time period. Blood ammonia level remained unchanged in those without cirrhosis but increased in 1 case with cirrhosis. Thus, appropriate attention should be paid to the metabolic derangements occurring during the 1st 2 to 3 postoperative weeks after hepatic dearterialization.

7960 HEPATIC NEUROPATHY: A CLINICAL AND ELECTROPHYSIOLOGICAL STUDY. *(E.)* Kardel, T.; Nielsen, V. K. (Gentofte Hosp., Copenhagen, Denmark). *Acta Neurol. Scand.* 50(4):513-526, 1974.

The frequency and distribution of impaired nerve function were studied in 34 patients (16 women and 18 men, aged 21-68 yr) with severe chronic hepatic failure, 20 of whom had a surgical portacaval shunt. Clinical symptoms and signs were present in 23 patients and absent in 11. Eight patients complained of paresthesia in the feet, in 6 the ankle jerks were absent and the knee jerks absent or decreased, and in 21 the vibratory perception threshold (VTP) on the big toe was elevated. However, the nerve function of the arm was also impaired. During ischemia the rise in VTP on the index finger was delayed in 18 patients, including 7 without other clinical signs of neuropathy. In 14 patients, conduction velocity was decreased in the digit-wrist and the wrist-elbow sections of the median nerve; the decrease was accompanied by a reduction in amplitude and an increase in temporal dispersion of the action potentials. Only 6 of the 14 patients showed conduction velocity values below the lower normal limit. Average nerve conduction values in patients with (9) and without (5) a shunt did not differ significantly. In 8 patients the sensory threshold for electrical stimuli (digit 3) was elevated. There was no relation between impaired nerve function and routine liver function tests or the galactose elimination capacity, a measure of the functioning liver mass. Neurological findings occurred with equal frequency in patients with and without chronic alcoholism or a diabetic glucose tolerance test. The frequency of impaired nerve function indicates that a peripheral nerve dysfunction is an integral part of the severe chronic hepatic failure syndrome. The distribution of findings suggests that hepatic neuropathy results from metabolic inhibition of the nerve axon membrane function.

7961 DEGRADATION OF HUMAN α_1-ANTITRYPSIN BY HEPATOCYTE ACID CATHEPSINS: POSSIBLE ROLE IN CLINICAL α_1-ANTITRYPSIN DEFICIENCY. *(E.)* Sandhaus, R. A.; Janoff, A. (Hlth. Sci. Ctr., State Univ. New York, Stony Brook). *Am. Rev. Respir. Dis.* 110(3):263-272, 1974.

α_1-Antitrypsin was studied as an inhibitor or conversely as a substrate of hepatocyte lysosomal acid cathepsins. Granule hydrolases from hepatocyte-enriched preparations of the livers of fetal, neonatal, and adult rabbits were interacted at pH 3.0 with a fraction of human serum containing a molar excess of α_1-antitrypsin. In addition, a human liver was examined in a similar way. All granule extracts tested produced degradation of human serum proteins, including α_1-antitrypsin, within 1 hr as monitored by immunoelectrophoretic analysis. It was concluded that α_1-antitrypsin does not inhibit hepatocyte acid cathepsins at any of the stages of liver development tested, but rather that this serum glycoprotein is degraded by these acid proteases. In light of these findings, the most likely mechanism for intracellular α_1-antitrypsin accumulation involves hypersynthesis of α_1-antitrypsin as a result of lowered serum concentrations due to the lack of α_1-antitrypsin release from the endoplasmic reticulum. This model is supported by previously reported clinical findings.

7962 REYE'S SYNDROME. *(E.)* Brown, T.; Hug, G.; Bove, K.; Brown, H.; Lansky, L. (Children's Hosp. Res. Fdn., Cincinnati, Ohio). *Lancet* (7882):716-717, 1974.

The activity of ornithine transcarbamylase and carbamyl-phosphate synthetase in hepatic specimens from 4 patients with Reye's syndrome are reported. Mean activity of ornithine transcarbamylase and carbamyl-phosphate synthetase in Reye's syndrome was reduced to 37% and 57% of normal, resp. The activity for ornithine transcarbamylase was outside the 95% confidence limits of normal in one patient, and that for carbamyl-phosphate synthetase in two patients. In these cases, therapy with ornithine or arginine might be counterproductive.

7963 FOLLOW-UP OF PATIENT WITH PORTACAVAL SHUNT FOR THE TREATMENT OF HYPERLIPIDAEMIA. *(E.)* Starzl, T. E.; Chase, H. P.; Putnam, C. W.; Nora, J. J. (Univ. Colorado Med. Ctr., Denver). *Lancet* (7882):714-715, 1974.

A 17-month follow-up of a 12-yr-old girl with type IIa hyperlipoproteinemia who underwent end-to-side portacaval shunt in an attempt to lower cholesterol levels is reported. The patient had had a myocardial infarction prior to surgery. The preoperative angina pectoris has not recurred. Serum cholesterol levels have remained below 400 mg/100 ml. The mean postoperative serum cholesterol level has been 330 mg/100 ml, compared to a mean of 769 mg/ml prior to surgery. Coronary arteriograms obtained three months before the portacaval shunt revealed diffuse narrowing of the coronary arteries, and the circumflex artery was not displayed. Coronary studies 16 months after portacaval shunt revealed no diffuse narrowing in any of the three coronary arteries. The general internal dimensions would be considered normal except for three discrete areas of occlusive disease. It is suggested that homozygous type II patients who show evidence of cardiovascular disease and who have not adequately responded to lipid-lowering medication be considered for the portacaval shunt.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

7988 AN ENZYME INDUCTOR COMBINATION FOR THE PREVENTION OF HYPERBILIRUBINEMIA IN PREMATURE INFANTS. *(E.)* Hinkel, G. K.; Kintzel, H. W.; Schwarze, R.; Handel, A. (Pediatr. Hosp., Dresden, Germany). *Acta Paediatr. Scand.* 63(3):393-397, 1974.

The effectiveness of phenobarbital and nikethamide, an enzyme inductor combination, in controlling physiologic hyperbilirubinemia in premature infants was studied. The infants were divided into 5 groups: Group I infants were given phenobarbital (10 mg/kg/day for 6 days); group II, phenobarbital (10 mg/kg/day) plus nikethamide (100 mg/kg/day) each for 6 days; group III, phenobarbital (10 mg/kg) plus nikethamide (25 mg/kg) at the 12th, 24th, and 36th hr of age; group IV, phenobarbital (20 mg/kg on day 1, 10 mg/kg on days 2 and 3) plus nikethamide (100 mg/kg/day, days 1-4); group V, phenobarbital (10 mg/kg/day, days 1-3) plus nikethamide (100 mg/kg/day, days 1-4). All medication was given p.o. The bilirubin-depressive effect of phenobarbital combined with nikethamide was stronger than that of phenobarbital alone. Short-term induction using phenobarbital plus nikethamide was accompanied by the highest bilirubin concentrations. The sedative action of phenobarbital was adequately offset by nikethamide when used in combination dosages of 10 mg/kg and 100 mg/kg, resp. Nikethamide did not cause irritability. However, long-term application was followed by an emerging dominance of barbiturate action which was attributed to phenobarbital accumulation. The combination used in group III appeared ineffective. Group IV suffered a marked barbiturate effect. The combination used in group V was well tolerated, and prophylactic routine use of the enzyme inducer combination in this manner is the recommended method to prevent development of hyperbilirubinemia in premature infants. Exchange transfusion was no longer necessary in 400 premature infants who received this combination. However, phototherapy is considered the most suitable method to treat a pre-existing hyperbilirubinemia.

7989 EFFECT OF PHENOBARBITONE ON PHYSIOLOGICAL JAUNDICE. *(E.)* Singh, M.; Naryanan, P. (All India Inst. Med. Sci., New Delhi). *Indian Pediatr.* 11(1):43-45, 1974.

A prospective controlled trial was conducted to assess the efficacy of postnatal administration of phenobarbital for its bilirubinopenic effects. Sodium phenobarbital (7.5 mg twice a day, p.o., starting at 12 hr of age) was administered to 65 of 130 babies with birth weight over 2200 g. The remaining 65 infants served as controls. The mean total serum bilirubin on day 4 was 5.01 mg% in babies receiving phenobarbital; 6.06 mg% in controls. The unconjugated bilirubin was significantly lower in infants receiving phenobarbital; the level of conjugated bilirubin was higher, but not significantly so. The greater reduction of unconjugated bilirubin suggests that hepatic uptake and conjugation of bilirubin were promoted by phenobarbital treatment. Of the 65 infants receiving phenobarbital, 41 (63%) developed clinical jaundice (bilirubin over 4 mg%) compared with 50 babies (77%) in the control group. Serum bilirubin did not exceed 10 mg% in any babies receiving phenobarbital, but did so in 5 control babies. No side effects such as inactivity, poor feeding, excessive sleep, respiratory depression or aspiration were noted in any baby receiving phenobarbital. Despite its bilirubinopenic effectiveness, the routine use of phenobarbital is not recommended in term babies. It should be restricted to cases of feto-maternal blood group incompatability and immaturity.

7990 HEPATIC MICROSOMAL DRUG OXIDATION AND ELECTRON TRANSPORT IN NEWBORN INFANTS. *(E.)*

Aranda, J. V.; MacLeod, S. M.; Renton, K. W.; Eade, N. R. (Montreal Child. Hosp., Canada). *Pediatr. Pharmacol. Ther.* 85(4):534-542, 1974.

The activities of drug-metabolizing enzymes, NADPH cytochrome c reductase, NADPH oxidase, aminopyrene-*N*-demethylase, and aniline-*p*-hydroxylase, as well as cytochrome P-450 levels, were measured in liver microsomal fractions from 4 premature and 3 newborn infants and from 4 adults. All the above-mentioned enzymes, except aminopyrene-*N*-demethylase, showed increasing specific activity with advancing fetal and postnatal age. A positive correlation was found between 3 components of the hepatic microsomal mixed function oxidase system (NADPH oxidase, NADPH cytochrome c reductase, and cytochrome P-450) and aniline-*p*-hydroxylase. However, only NADPH oxidase activity correlated with aminopyrene-*N*-demethylase activity. The rate of substrate oxidation and the activities of the components of the microsomal electron transport pathway in newborns were lower than comparable values in the adults. These findings provide a possible explanation for the transient deficiency in drug metabolism seen in newborn infants.

7991 DRUGS AND THE LIVER - I. EFFECTS OF GLUTETHIMIDE AND PHENOBARBITAL ON HEPATIC BILIRUBIN CLEARANCE, PLASMA BILIRUBIN TURNOVER AND CARBON MONOXIDE PRODUCTION IN MAN. *(E.)*

Blaschke, T. F.; Berk, P. D.; Rodkey, F. L.; Scharschmidt, B. F.; Collison, H. A.; Waggoner, J. G. (Natl. Cancer Inst., NIH, Bethesda, Md.). *Biochem. Pharmacol.* 23(20):2795-2806, 1974.

The effects of glutethimide and phenobarbital (2-4 mg/kg/day) on the plasma unconjugated bilirubin concentration, hepatic bilirubin clearance, and plasma bilirubin turnover were determined in 19 patients (14 males and 5 females) with mild chronic unconjugated hyperbilirubinemia (Gilbert's syndrome) and 11 normal volunteers. Hepatic bilirubin clearance and plasma bilirubin turnover were calculated from plasma radiobilirubin disappearance curves obtained before and during drug administration. The response to both drugs was essentially identical. During administration, the patients with Gilbert's syndrome attained a new steady state in which the plasma unconjugated bilirubin concentration was 30 ± 2% and the hepatic bilirubin clearance was 314 ± 25% of baseline. In normal volunteers, the plasma unconjugated bilirubin concentration fell to 65 ± 6% while the hepatic bilirubin clearance increased to 135 ± 9% of baseline during drug administration. Although neither total red cell volume nor the half-life of ^{51}Cr-labeled erythrocytes was altered by either agent, daily plasma bilirubin turnover fell significantly to 87 ± 4% of baseline in the 30 subjects studied, and endogenous carbon monoxide production, which provides an independent estimate of the rate of heme degradation and bilirubin formation, was 93 ± 5% of control. These results indicate that the principal factor responsible for the reduction in plasma unconjugated bilirubin concentration during phenobarbital or glutethimide administration is the acceleration of hepatic bilirubin clearance. This accounts for more than 95% of the reduction in bilirubin concentration observed in patients with Gilbert's syndrome and an average of 70% of the reduction noted in normal volunteers. This is the first study to detail quantitative alterations in hepatic bilirubin clearance produced in a large number of individuals by drugs. The observation of an inverse relationship between baseline values for bilirubin clearance and the percentage increase in this parameter achieved during drug administration suggests that the drug effects are related to induction of a protein whose level is under genetic control. No association between phenobarbital or glutethimide administration and increased bilirubin or carbon monoxide production was noted. The possibility that a fall in the load of bilirubin presented to the liver might contribute to the reduction in plasma bilirubin concentration during drug administration is an important new observation. Use of these agents may increase the efficiency of the liver in excreting the bilirubin of hepatocellular origin directly into the bile without prior reflux to the plasma.

7992 PLASMA CONCENTRATIONS OF PHENOBARBITAL IN THE NEONATE DURING PROPHYLAXIS FOR NEONATAL HYPERBILIRUBINEMIA. *(E.)*

Wallin, A.; Jalling, B.; Boreus, L. O. (Danderyd Hosp., Stockholm, Sweden). *J. Pediatr.* 85(3):392-397, 1974.

Plasma concentrations of phenobarbital were measured during a routine prophylaxis program. Eleven newborn infants without signs of disease during the first hours of life were given a first meal (5% glucose) at the age of 4 hr and thereafter increasing amounts of breast milk from about 25 mg/kg on day 1 to about 100 mg/kg on day 8, in some cases replaced by equal amounts of formula. Each infant received a first dose of phenobarbital (5 mg/kg, i.m.) at 1-4 hr of age. On days 2 to 7 phenobarbital (5 mg/kg, p.o.) was given once daily. Daily determinations of plasma phenobarbital were made with a gas chromatographic micromethod. The total plasma concentration of phenobarbital increased throughout the period of treatment. Steady-state conditions were not generally achieved. The phenobarbital peak level in plasma always occurred later than that of bilirubin. The individual plasma curves show striking conformity during the week of phenobarbital administration, suggesting uniform intestinal absorption in these infants. The half-lives of the drug during post-treatment phase varied between 69 and 165 hr. The rate of disposition from plasma was not related to age of gestation, recorded maternal medication, or smoking habits, nor to the maximum plasma concentrations of phenobarbital and/or bilirubin in the infant. Plasma concentrations of phenobarbital during the last days of treatment ranged between 20 and 30 μg/ml. No obvious adverse effects were noted. However, minor effects on the behavior of the infants such as changes in feeding times or in spontaneous activity could not be excluded. It is suggested that dosage regimens should be so constructed that the drug may exert its maximal effect on bilirubin concentration very early after birth.

7993 INFLUENCE OF PREVIOUS ORAL CONTRACEPTION AND MATERNAL OXYTOCIN INFUSION ON NEONATAL JAUNDICE. *(E.)* Gould, S. R.; Mountrose, U.; Brown, D. J.; Whitehouse, W. L.; Barnardo, D. E. (Queen Mary's Hosp., London, England). *Br. Med. J.* 3(5925): 228-230, 1974.

The relation between maternal and neonatal serum bilirubin levels, maternal oral contraceptive history, maternal exposure to oxytocic agents immediately preceding delivery, and the method of feeding in the first six days of life was investigated in 181 mothers and neonates. Oxytocin (Syntocinon) was administered i.v. to 100 of the mothers as a routine measure to expedite delivery. Epidural anesthesia with bupivacaine was used in 109 of the mothers at the time of delivery. No differences were found on day 1 or day 6 between the neonatal serum bilirubin levels in babies grouped according to maternal oral contraception history and method of feeding. A comparison between the serum bilirubin levels of babies whose mothers had stopped taking oral contraceptives 3 months or less before conception and those whose mothers had stopped contraceptives more than 3 months before conception showed no significant differences. Nor was a difference noted when these 2 groups were compared to babies whose mothers did not use oral contraceptives at all. Neither the use of oxytocin during labor nor the use of epidural anesthesia influenced the neonatal serum bilirubin level. There was no difference in serum bilirubin level between breast-fed and bottle-fed infants, nor did birth weight seem to be of importance. It was noted that breast-fed babies born to mothers previously taking oral contraceptives were slightly but significantly heavier by about 250 g.

7994 PHOTOTHERAPY, PHENOBARBITONE AND PHYSIOLOGICAL JAUNDICE IN THE NEWBORN INFANT. *(E.)* Martin, J. R. (Natl. Women's Hosp., Auckland, New Zealand). *NZ Med. J.* 79(517):1022-1024, 1974.

A clinical trial was conducted in which the effects of phototherapy and phenobarbital administration on serum bilirubin levels were determined in infants who had developed clinically apparent jaundice due to physiological causes. The infants were divided into 3 groups: group 1 (35 infants) received only routine nursery care; group 2 (34 infants) received routine care plus continuous phototherapy; group 3 (31 infants) received routine care and continuous phototherapy plus phenobarbital administered at 8 doses of 8 mg/hr if the birth weight was 3 kg or more, or 8 doses of 2 mg/kg/hr if the birth weight was under 3 kg. The initial dose was given i.m.; subsequent doses, p.o. A significant reduction in the maximum bilirubin level was achieved in both groups having phototherapy when compared to controls, but the administration of phenobarbital was without additional benefit. Maximum bilirubin levels were reached significantly earlier in both groups having phototherapy. The duration of phototherapy required was not significantly different between groups 2 and 3. Exchange transfusion was required for 3 babies in group 1, none in group 2, and 1 in group 3. Respiratory depression was no more frequent in groups 2 and 3 than in group 1. No cases of abnormal pigmentation as a result of phototherapy were noted; however, in all cases the hyperbilirubinemia was predominantly of the indirect type. On occasions the premature discontinuation of phototherapy caused a rise in the bilirubin level, usually of small magnitude. Under the conditions of this trial, phenobarbital administration begun after an infant has become jaundiced due to physiological causes appears of no significant benefit, while the regimen of phototherapy described here was of significant benefit in the control of hyperbilirubinemia due to physiological causes. However, the long term effect of phototherapy on the growth and development of treated babies has not yet been adequately evaluated.

7995 EFFECT OF PHOTOTHERAPY IN PRETERM INFANTS ON GROWTH IN THE NEONATAL PERIOD. *(E.)* Wu, P. Y. K.; Lim, R. C.; Hodgman, J. E.; Kikosky, M. J.; Teberg, A. J. (Univ. Southern California Sch. Med., Los Angeles). *J. Pediatr.* 85(4):563-566, 1974.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

7996 AN INDUSTRIAL OUTBREAK OF TOXIC HEPATITIS DUE TO METHYLENEDIANILINE. *(E.)* McGill, D. B.; Motto, J. D. (Mayo Clin., Rochester, Minn.). *N. Engl. J. Med.* 291(6):278-282, 1974.

Over a 6-yr period, hepatitis developed in 12 male workers (aged 20-36 yr) exposed to an epoxy resin, *p,p*'-diaminodiphenylmethane. The clinical pattern was a short prodrome, severe right upper-quadrant pain, high fever, and chills, with subsequent jaundice. All patients recovered by 7 weeks; and when reexamined 9 months to 5 1/2 yr later, all were in excellent health without clinical or biochemical evidence of chronic liver disease. Circumstantial evidence suggested that the skin was the major route of entry: each worker had at least 1 hand in *p,p*'-diaminodiphenylmethane for several hr during an 8-hr shift. The cloth gloves worn by the workers are ineffective barriers to aromatic amines. A 13th worker in another factory also had hepatitis after working with *p,p*'-diaminodiphenylmethane; he may have inhaled toxic amounts. Although *p,p*'-diaminodiphenylamethane is cirrhotogenic, there is little evidence that it is carcinogenic in animals. Therefore, it is unlikely that the chance of cancer developing in the workers had been increased by the exposure and toxic hepatitis.

7997 TOLAZAMIDE HEPATOTOXICITY. *(E.)* Van Thiel, D. H.; De Belle, R.; Mellow, M.; Widerlite, L.; Philipps, E. (Boston Univ. Sch. Med., Mass.). *Gastroenterology* 67(3):506-510, 1974.

The first case of documented hepatocellular toxicity secondary to the oral hypoglycemic agent, tolazamide, is reported in a 62-yr-old man with a 9-yr history of diabetes. The patient developed clinical jaundice 1 month after starting tolazamide (500 mg/day). He was otherwise asymptomatic and denied exposure to jaundiced persons, shellfish, parenteral drugs, or alcohol. Physical examination revealed jaundice and slight hepatomegaly. The patient had a negative test for α_1-fetoprotein, 5'-nucleotidase, and Australia antigen. Liver scan was normal. Duodenoscopy with retrograde cannulation showed a patent common bile and pancreatic duct. Percutaneous liver biopsy showed marked centrilobular necrosis with prominent pigment phagocytosis but no Councilman-like bodies. There was prominent centrilobular cholestasis. Jaundice persisted for 2 months after tolazamide was discontinued.

7998 CRYPTOCOCCAL HEPATITIS MIMICKING PRIMARY SCLEROSING CHOLANGITIS. *(E.)* Lefton, H. B.; Farmer, R. G.; Buchwald, R.; Haselby, R. (Cleveland Clin. Fdn., Ohio). *Gastroenterology* 67 (3):511-515, 1974.

A case of cryptococcal hepatitis which initially mimicked primary sclerosing hepatitis is reported in a 25-yr-old man. The patient initially presented with anorexia, vomiting, and right upper quadrant pain not related to meals. Physical examination revealed scleral icterus, right upper quadrant tenderness, and no hepatosplenomegaly. Laparatomy showed thickened cystic and common ducts and small yellowish nodules on the liver surface and on a periductal lymph node. Liver biopsy revealed disruption of normal architecture with extensive inflammatory infiltrate and cholestasis. There was no liver necrosis. The patient was placed on prednisone (40 mg/day followed by 20 mg/day) maintenance therapy postoperatively but was readmitted 1 month later with generalized cephalgia, agitation, and disorientation. India ink preparation of spinal fluid obtained by lumbar puncture showed cryptococcus. Spinal fluid cultures grew *Cryptococcus neoformans*. Repeat study of the original liver biopsy specimen after using Gridley's stain for fungi showed encapsulated yeast-like organisms. The patient was treated successfully with intrathecal and i.v. amphotericin B (15.65 mg and 279 mg, resp.) and p.o. 5-fluorocytosine (379.5 g). Repeat liver biopsy was negative.

7999 METHYLDOPA LIVER DAMAGE. *(E.)* Toghill, P. J.; Smith, P. G.; Benton, P.; Brown, R. C.; Matthews, H. L. (Gen. Hosp., Nottingham, England). *Br. Med. J.* 3(5930):545-548, 1974.

Twenty patients are described in whom liver damage appeared to be directly related to the administration of methyldopa. Sixteen had hepatitic syndromes from which all but one recovered within 3 weeks after stopping methyldopa; the exception recovered after 2 months. Four of the patients had recurrences of jaundice after a second course of the drug. Features suggestive of active chronic hepatitis were found in 2 patients. There were 2 deaths attributed to methyldopa, 1 of these being in a patient with preexisting undiagnosed macronodular cirrhosis. These findings show that methyldopa is undoubtedly hepatotoxic. The nature of the hepatic response to methyldopa remains obscure; the results of this series point to a wide spectrum of reactions both clinically and histologically.

8000 CHOLESTATIC JAUNDICE DUE TO METHYLDOPA. *(E.)* Hoffbrand, B. I.; Fry, W.; Bunton, G. L. (Whittington Hosp., London, England). *Br. Med. J.* 3(5930):559, 1974.

A case report is presented of a 51-yr-old woman known to have hypertension for a number of years and who developed cholestatic jaundice following administration of methyldopa. After taking methyldopa 250 mg 3 times daily for two months, the patient was found to be jaundiced with a just palpable, nontender liver; there was no fever, the spleen and gallbladder were not palpable, and there were no signs of hepatocellular dysfunction or hypertensive vascular disease. One week after discontinuing the drug, serum bilirubin was 18 mg/100 ml and another week later was 23.4 mg/100 ml compared to 11.3 mg/100 ml prior to drug discontinuance. Within another week, the serum bilirubin was 20 mg/100 ml. At laparotomy the liver and extrahepatic bile ducts looked normal; the spleen was not enlarged. The patient made an uneventful recovery and the jaundice gradually receded. Within three months of drug withdrawal, the serum bilirubin was 1.1 mg/100 ml with normal liver enzymes and no bile in the urine. Although the patient's jaundice deepened after withdrawal of the drug it was probably about to remit at the time of the laparotomy which might have been prevented had it been known that methyldopa can produce cholestatic jaundice.

8001 ONSET OF POSTOPERATIVE JAUNDICE RELATED TO ANAESTHETIC HISTORY. *(E.)* McPeek, B.; Gilbert, J. P. (Massachusetts Gen. Hosp., Boston). *Br. Med. J.* 3(5931):615-617, 1974.

An analysis of 182 cases (67 fatal and 115 nonfatal) from the U.S. National Halothane Study showed the interval to the onset of jaundice after one exposure to halothane (91 cases) to be significantly shorter

(1.5 days) than the interval for those having had multiple exposures to the agent. These findings are in contrast to other recently published results possibly because the data in the four published reports examined were drawn from voluntary input with no control over bias. Thirty-three cases of jaundice after the use of other anesthetic agents are also reported.

8002 METHODOLOGY OF EPIDEMIOLOGIC STUDIES ON DRUG HEPATOTOXICITY.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

8003 HEPATIC WASH-OUT CURVES OF ^{85}Kr AND ^{133}Xe AFTER RETROGRADE HEPATIC VENOUS INJECTIONS IN PATIENTS WITH INFECTIOUS HEPATITIS AND IN CONTROLS.

(E.) Lundbergh, P.; Strandell, T. (Roslagstull Hosp., Stockholm, Sweden). *Scand. J. Clin. Lab. Invest.* 33(3):277-285, 1974.

The disappearance rates of ^{85}Kr and ^{133}Xe from the liver after their administration by retrograde simultaneous hepatic venous injection were studied in 8 male patients with infectious hepatitis and 10 healthy male controls. Since xenon has a higher affinity than krypton for fat, the quotient between the half-times of the two labels was used to calculate the hepatic fat content as well as the partition coefficients of the isotopes between the hepatic tissue and blood. The estimated hepatic fat content was significantly higher in the hepatitis patients (5.8%) than in the controls (3.6%). Among the patients, the hepatic fat content was highest in those with the least severe abnormal findings. The partition coefficients of krypton and xenon were 1.09 and 1.13, resp., in the controls and 1.25 and 1.41, resp., in the patients. The differences were significant. The isotope clearances seemed to overestimate the average perfusion coefficient by 25% as indicated by the total hepatic blood flow data and expected liver weights; this might be explained in terms of local hyperemia in the injected areas. This method can be efficaciously used to estimate partition coefficients and hepatic fat content.

8004 THE ROLE OF IMMUNOLOGICAL MECHANISMS IN ACUTE AND CHRONIC HEPATITIS.

(E.) Eddleston, A. L. W. F. (King's Coll. Hosp., London, England). *Postgrad. Med. J.* 50(584):348-353, 1974.

Carriers of hepatitis B antigen (HBAg) include apparently healthy persons, a proportion of whom have asymptomatic liver disease. The frequency of the carrier state increases with immunological deficiency. The fact that a symbiotic union can exist implies that the hepatitis B virus itself is not damaging to liver cells and that the hepatocellular damage in some patients with acute hepatitis is associated with some indirect mechanism triggered by the presence of the virus. Preliminary findings support the possibility that the hepatocellular necrosis which accompanies acute hepatitis may be induced by immunological reactions directed against viral antigenic determinants on the surface of infected cells. Immunological reactions may also be implicated in the pathogenesis of active chronic hepatitis. A liver-specific antigen has recently been isolated from the human liver; it is a lipoprotein thought to be a normal constituent of the hepatocyte plasma membrane. Sensitization to this lipoprotein has been found in a high percentage of patients with active chronic hepatitis, the incidence of sensitization being much higher among patients not being treated with immunosuppressive drugs. Sensitization has been detected in only a very low percentage of control subjects. Hypothetically, an altered liver-specific protein induced by an exogenous stimulus might cross react with the normal protein leading to increasing liver cell destruction; the autoimmune reaction might be vigorous and long-lasting in cases of an abnormal immune system.

8005 SUBTYPE AND TRANSMISSION OF HEPATITIS B VIRUS IN TWO CLOSED INSTITUTIONS.

(E.) Edlund, A.; Magnius, L. O. (Acad. Hosp., Uppsala, Sweden). *Scand J. Infect. Dis.* 6(3):217-221, 1974.

In less than 1 yr, 5 cases of hepatitis B occurred among patients and staff at an institution for the mentally retarded. The common source of infection was thought to be the only carrier of hepatitis B antigen (HBAg) among 13 patients with Down's syndrome. Five months before the 1st case of hepatitis B, this patient had been transferred from another institution where 10 cases of hepatitis B occurred before or within 4 months after her transfer. An 11th patient became ill with hepatitis B 2 yr after she left. All 16 patients and the presumed source of infection were HBAg-positive and carried the subtype *ad*. This subtype was also found in 3 HBAg-positive patients with Down's syndrome at the 2nd institution and in 63 HBAg carriers at 5 other institutions. Persistent HBAg carriers among patients with Down's syndrome evidently present a great risk for transmitting hepatitis B in contrast to healthy carriers in the normal population. An immunodeficient state in Down's syndrome patients might be the cause of antigenemia in Down's syndrome being associated with hepatocellular injury and persistence of infectivity. This immunodeficiency state is presumably also the basis for the absence of overt hepatitis in these carriers. The exclusive occurrence of subtype *ad* at institutions for the mentally retarded contrasts with the predominance of subtype *ay* among cases of acute hepatitis B in Sweden.

8006 ROLE OF HEPATITIS-B ANTIGEN CARRIERS IN NON-PARENTERAL TRANSMISSION OF THE HEPATITIS-B VIRUS. *(E.)* Heathcote, J.; Gateau, P.; Sherlock, S. (Roy. Free Hosp., London, England). *Lancet* (7877):370-371, 1974.

Tests for hepatitis B antigen (HBAg) and hepatitis B antibody (HBAb) were run on sera from 54 household contacts of 29 HBAg carriers. Of the carriers, 11 were presumed "healthy" since they had no clinical or biochemical evidence of impaired liver function although they remained HBAg-positive for 6 months or more. The remaining carriers either had cirrhosis (12 cases) or chronic persistent hepatitis (6 cases). Controls consisted of 29 age- and sex-matched volunteers and 61 household contacts. While none of the household contacts of the 11 "healthy" carriers were HBAg-positive and only 1 contact was HBAb-positive, 3 of the 35 contacts of HBAg-positive subjects with chronic liver disease were HBAg-positive and 13 of the other contacts were HBAb-positive. All 29 controls and their household contacts were HBAg-negative and, except for 1 contact, none were HBAb-positive. Statistical analysis of serological results revealed that the contacts of carriers with chronic liver disease were at greater risk of presumed non-parenteral exposure to HBAg than were contacts of "healthy" HBAg carriers. This was most often demonstrated by the presence of HBAb, sometimes in high titers, in sera from contacts of HBAg carriers with chronic liver disease. Although it has been suggested that the greater infectivity of blood from HBAg carriers with chronic liver disease may be due to the presence of more circulating large Dane particles than are present in blood from "healthy" carriers, electron microscope studies of sera from several HBAg carriers, both "healthy" and with chronic liver disease, failed to show any correlation between the type of carrier and the presence of Dane particles. HBAg and HBAb were more commonly found in sera from sexual contacts of HBAg carriers than in sera from blood relative contacts, but the difference in findings between these 2 groups of contacts was not statistically significant.

8007 HEPATITIS B AND SERUM DNA POLYMERASE ACTIVITIES IN CHIMPANZEES. *(E.)* Bradley, D. W.; Maynard, J. E.; Berquist, K. R.; Krushak, D. H. (Ctr. Dis. Control, Phoenix, Arizona). *Nature (Lond.)* 251(5473):356-357, 1974.

Four susceptible chimpanzees were inoculated i.v. with sera containing hepatitis B antigen and monitored by radioimmunoassay for serum HBAg and corresponding antibody during the course of infection. Three developed infections characterized by the occurrence of transient HBAg followed by anti-HBAg production. In all 4 animals spikes of DNA polymerase activity were found, the 1st increases being uniformly observed between the 20th and 40th days after inoculation. In the 3 animals which experienced antigenemia and hepatitis, the 1st spikes in DNA polymerase either closely preceded or paralleled the 1st appearance of HBAg and always occurred before 1st increases in transaminase levels. These spikes may represent replication of viral DNA. The postulated viral DNA polymerase activity seems to depend on a DNA template rather than on an RNA template. The detection of increased DNA polymerase activity in an infected animal which showed no clinical, enzymatic or immunological evidence of hepatitis during the first 70 days after inoculation suggests that the DNA polymerase assay may be useful in screening potentially infective sera.

8008 ACQUISITION OF HEPATITIS B ANTIGEN IN THE NEWBORN PERIOD. *(E.)* Cossart, Y. (Centr. Public Hlth. Lab., London, England). *Postgrad. Med. J.* 50(584):334-337, 1974.

Newborns with mothers who had contracted Australia antigen-positive hepatitis during pregnancy were studied and the incidence of hepatitis was determined. Only 3 infants escaped infection: one whose mother contracted hepatitis early in pregnancy and 2 whose mothers had contracted hepatitis near delivery but who were separated from their mothers after birth. The other 3 babies became antigen positive shortly after birth and have remained long-term carriers. Their liver function tests became abnormal, but they have remained clinically well. Mothers of these infants contracted hepatitis at the time of delivery or shortly thereafter. Liver biopsy of 1 child with antigen-positive serum whose mother had contracted hepatitis at delivery confirmed the presence of hepatitis. In another series of 3 mothers who were Australia antigen carriers, none of the infants was affected. Review of the literature showed that of 28 babies with Australia antigen-positive hepatitis, 80% were born to mothers who had acute antigen-positive hepatitis late in pregnancy or in the puerperium. For over half, the onset coincided with delivery. Neonatal hepatitis, however, seldom occurs in infants whose mothers are carriers or who had hepatitis early in pregnancy.

LIVER AND BILIARY TRACT

Chronic Hepatitis

8023 TOTAL PLASMA BILE ACID CONCENTRATION IN CHRONIC HEPATITIS AND CIRRHOSIS: FASTING VALUES AND EFFECT OF INTRADUODENAL BILE SALT ADMINISTRATION. *(E.)* Franz, B.; Bode, J. C. (Med. Clin., Univ. Marburg, Germany). *Klin. Wochenschr.* 52(11): 522-526, 1974.

Enzymatic determinations of total fasting plasma bile acid concentrations were performed on 35 patients with various forms of cirrhosis, 11 with chronic aggressive hepatitis, 25 with chronic persistent hepatitis, and on 24 controls with no history or clinical evidence of liver disease. Mean values for plasma bile acid concentrations were 40.7 ± 32.5 μM/liter for cirrhotics, 34.2 ± 18.5 μM/liter for patients with chronic aggressive hepatitis, 5.93 ± 4.7 μM/liter for those with chronic persistent hepatitis, and 4.23 ± 2.26 μM/liter for controls. Plasma bile acid concentrations were markedly increased in 80% of the cirrhotics and were above the normal range in all 11 patients with chronic aggressive hepatitis. In contrast, only 25% of the patients with chronic persistent hepatitis had slightly elevated plasma bile acid concentrations. Except for 3 patients with primary biliary cirrhosis who had levels of 80 μM/liter or above, no differences were found between patients with various forms of cirrhosis. No correlation was found between plasma bile acid concentrations and SGOT, SGPT, alkaline phosphatase, serum cholesterol, γ-globulin, decrease in serum albumin concentrations, or the prothrombin time. A positive correlation was observed between plasma bile acid and serum bilirubin concentrations. During a 24-hr period only minor variations occurred in plasma bile acid concentrations in controls, but they increased during the day and returned to fasting values thereafter in 3 of 5 patients with chronic liver disease. Injection of cholecystokinin (1 U/kg i.v.) had little effect on plasma bile acid concentrations in controls but produced significant increases in 4 of 7 patients with chronic liver disease. The failure of cholecystokinin to increase plasma bile acid concentrations in some patients with chronic liver disease is attributed to impaired gallbladder function. Intraduodenal administration of 2 g taurocholate increased plasma bile concentrations in all patients with chronic liver disease but not in controls. The largest increases occurred in patients with the highest fasting plasma bile acid concentrations. No correlation was found between plasma bile acid concentrations and pruritis.

8024 ALPHA$_1$-FETOPROTEIN IN CHRONIC LIVER DISEASE.

(E.) Silver, H. K. B.; Gold, P.; Shuster, J.; Javitt, N. B.; Freedman, S. O.; Finlayson, N. D. C. (Montreal Gen. Hosp., Canada). *N. Engl. J. Med.* 291(10):486-490, 1974.

The production of α_1-fetoprotein and the occurrence of circulating hepatitis B antigen (HBAg) were studied in 171 patients with chronic liver disease whose diagnoses included: chronic HBAg carriers (13), persistent hepatitis (19), chronic active hepatitis (48), primary biliary cirrhosis (13), cryptogenic cirrhosis (28), alcoholic cirrhosis (37), and extrahepatic biliary obstruction (13). Of the total 171 patients, 24 had at least transient elevations of α_1-fetoprotein. Significantly, 16 of the 48 patients (33%) with chronic active hepatitis had elevated serum levels. These 16 patients had more active liver disease as reflected by definitely higher maximum SGOT concentrations, 780 IU/liter, compared with 339 IU/liter for chronic active hepatitis patients negative for α_1-fetoprotein. In addition, the 16 patients positive for α_1-fetoprotein were characterized by seronegativity for HBAg, while the chronic hepatitis patients negative for α_1-fetoprotein were characterized by seropositivity for HBAg. Of the 13 chronic HBAg carriers, only 2 were positive for α_1-fetoprotein. α_1-Fetoprotein levels fell and became undetectable when clinical and laboratory evidence of remission were observed. Of the 123 patients with diseases other than chronic active hepatitis, only 8 had α_1-fetoprotein elevations at any time. None of these 8 patients showed any association between seropositivity for α_1-fetoprotein and the severity of the histologic picture. No correlation was found between the detection of α_1-fetoprotein and the presence of serum autoantibodies, or the activity of the liver disease as reflected by serum transaminase levels in these 8 patients. α_1-Fetoprotein was not detected in any patient with either intrahepatic or extrahepatic biliary obstruction. The correlation of the elevated α_1-fetoprotein and the SGOT levels in 16 chronic active hepatitis patients may reflect a regenerative response on the part of the liver similar to that observed in patients with severe viral hepatitis. Thus, the increased production of α_1-fetoprotein may be associated with the manner of liver injury and the response to that injury rather than with the ultimate severity of the damage. Longitudinal surveillance of appropriate patient populations is needed to determine whether the coexistence of these 2 serologic abnormalities increases the risk of primary hepatoma in patients with chronic liver disease.

8025 TREATMENT OF ACTIVE CHRONIC HEPATITIS AND ACTIVE CIRRHOSIS WITH PENICILLAMINE.

(E.) Schnack, H. (no affil.). *Postgrad. Med. J.* 50(2):44, 1974.

Penicillamine (750 mg/day for 6 months) was used to treat 14 patients with active chronic hepatitis or active cirrhosis who showed high SGOT levels but experienced no jaundice. In a few instances the dose level was raised to 1250 mg/day for short periods. Azathioprine was also administered to 2 patients, 1 of whom received a corticosteroid as well. No improvement was noted in patients with Sjogren's syndrome. Penicillamine was well tolerated and brought about improved biochemical measurements in 8 patients, 4 of whom also showed histological improvement. For various reasons 6 patients did not complete 6 months on penicillamine and gained no benefit from the drug. One of these 6 developed a severe skin reaction at 3 months. No other important adverse reaction was noted. It is suggested that a controlled trial be conducted using penicillamine.

8026 THERAPEUTIC TRIALS WITH HETEROLOGOUS ANTI-Au (SH) GLOBULIN.

(Ger.) Tauchnitz, C.; Rogos, R.; von Baehr, R. (Med. Clin., Karl Marx Univ., Leipzig, Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 33(4/5):173-178, 1973.

Three patients with chronic liver disease (2 with cirrhosis and 1 with chronic active hepatitis) and positive tests for Australian antigen (AuAg) were treated with horse antiserum against AuAg in an attempt to neutralize the circulating antigen. Patients were first tested for allergies to horse serum. The antiserum, used as a 2% IgG solution, was infused i.v. in doses of 10-50 ml in 300 ml electrolyte solution. One of the patients received 50 ml/day antiserum on 3 successive days. No untoward reactions occurred, and the results of liver function tests (SGOT, SGPT, bilirubin, thymol turbidity, and serum alkaline phosphatase) remained essentially unchanged. However, AuAg titers did not decrease. Apparently, there were not enough Au antibodies to neutralize AuAg in these patients. This hypothesis is supported by the lack of change in β_1C-globulin concentrations which were determined before and after therapy in 2 of these 3 patients. It is also possible that circulating antibodies could not reach intracellular antigen.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

8033 DEATH RATES FROM LIVER CIRRHOSIS IN ALCOHOL MONOPOLY AND FREE-MARKET STATES. *(E.)* Andreano, R. L.; Li, J. Y. (Hlth. Economics Res. Ctr., Univ. Wisconsin, Madison). *Q. J. Stud. Alcohol.* 35(2):649-654, 1974.

At present 17 states restrict sales of alcoholic beverages through state monopolies. In 31 free-market states, retailers and wholesalers are licensed by the state. The adult male cirrhosis death rate/100,000 is 23.2 in the monopoly states and 30.8 in the free-market states. For cirrhosis with alcoholism, the respective rates are 7.5 and 11.3. Analysis based on 4 levels of absolute alcohol consumption shows that death from cirrhosis increases by 8.59/100,000 as alcohol consumption increases from 1.01-2.00 gal/capita to 2.01-3.00 gal/capita. At the 3.01-4.00 gal/capita level, the increase in mortality is 2 times higher than in the previous group. The increase declines at the 4.01-6.94 gal/capita level but is still higher than at the 1st level. A somewhat similar relation obtains for death rates from cirrhosis with alcoholism. Based on these results, a threshold level may exist, perhaps at around 4 gal/capita. Results of regression analysis indicate that a free-market state will have a higher mortality rate from cirrhosis than a monopoly state with an equal alcohol consumption level. The regression coefficients indicate that each gallon reduction in per capita alcohol consumption would produce a predicted mean change in male adult death rates of almost 12.8/100,000 in monopoly states and about 11.9/100,000 in free-market states.

034 PANCREATIC FUNCTION IN MALABSORBING ALCOHOLIC CIRRHOTICS. *(E.)* Moeller, D. D.; Dunn, G. D.; Klotz, A. P. (Univ. Kansas Med. Ctr., Kansas City). *Am. J. Dig. Dis.* 19(9):779-784, 1974.

A 6-month prospective study was performed to determine the frequency of malabsorption in alcoholic cirrhosis. Lundh test meals and pancreozymin-secretin tests were also performed to improve knowledge of pancreatic exocrine function in malabsorbing cirrhotics. Of 31 patients with suspected or proven cirrhosis, 15 had malabsorption. Only 6 of 19 with proven or suspected noncirrhotic alcoholic liver disease (fatty infiltration or alcohol hepatitis or both) had malabsorption. The 6 patients studied (5 men and 1 woman, aged 45-68 yr) were diagnosed as having portal cirrhosis and fatty metamorphosis, liver cell degeneration; septal cirrhosis; portal cirrhosis (3 cases); and cirrhosis of the liver with fecal liver-cell necrosis. Only one of these patients showed significant pancreatic exocrine insufficiency with variations from normal on both the pancreozymin-secretin test and the Lundh test meal. Chymotrypsin concentration plotted against time in the pancreozymin-secretin test showed that the 20-min specimen after the secretin test was significantly lower in cirrhotics. Enzyme concentration in the Lundh test meal showed that cirrhotics had significantly elevated concentrations in the first collection period after the test meal.

LIVER AND BILIARY TRACT

Cirrhosis

036 ESSENTIAL L-AMINO ACIDS FOR HYPERALIMENTATION IN PATIENTS WITH DISORDERED NITROGEN ETABOLISM. *(E.)* Abel, R. M.; Abbott, W. M.; Beck, r., C. H.; Ryan, Jr., J. A.; Fischer, J. E. (Massachusetts Gen. Hosp., Boston). *Am. J. Surg.* 128(3): 317-323, 1974.

The effects of hyperalimentation with a solution of hypertonic dextrose and 8 essential L-amino acids were studied in 139 patients with disordered nitrogen metabolism. Most patients (114) had acute renal failure either alone or in combination with acute hepatic failure (hepatorenal syndrome). Patients with chronic hepatic insufficiency without renal failure (7) or with azotemia (18) resulting from a variety of other conditions were also treated. Precautions were taken to avoid electrolyte imbalance during therapy. The most common complication was hyperglycemia (>300 mg%) which occurred at one time or another in 75 (54%) patients. All but 2 were easily treated with a temporary slowing of the infusion rate and/or insulin. Only one case of "hyperosmolar state" occurred. Catheter-related sepsis was documented in 2 patients and was treated by removal of the catheter. One patient developed pneumothorax and one patient with severe coagulopathy died after persistent bleeding from the subclavian venipuncture site. In general, although mortality remained high among the groups of poor-risk patients, hyperalimentation with the essential amino acids and dextrose produced subjective and objective improvement.

8037 THE SIGNIFICANCE OF MALLORY BODIES IN THE PROGRESSION OF FATTY LIVER INTO CIRRHOSIS.

(E.) Christoffersen, P.; Juhl, E. (Kommune Hosp., Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 82(4):483-486, 1974.

Two groups of patients with fatty changes of the liver seen on biopsy were studied: 16 patients with Mallory bodies and 67 patients without Mallory bodies. Eleven (69%) of the biopsies with Mallory bodies exhibited changes as seen in alcoholic hepatitis (necrosis of liver cells containing Mallory bodies with infiltration of neutrophils). The incidence of acidophil bodies, parenchymal inflammation, and parenchymal and portal fibrosis was greater in biopsies with Mallory bodies than in biopsies without Mallory bodies. There was no decisive difference in the incidence of lipogranulomas, lytic cell necroses, variation in size of nuclei and cells, portal inflammation, bile duct proliferation, cholestasis, iron content, and lipfuscin or degree of fatty change. Serum asparate-transaminase and BSP-retention were elevated in both groups of patients but were significantly higher in those with Mallory bodies. Repeat biopsies from 14 patients with Mallory bodies showed 3 with cirrhosis and 2 with suspicion of cirrhosis. The observation time for the 3 cases with cirrhosis was 8, 67, and 72 months, resp., and for the cases with suspicion of cirrhosis, 1 and 30 months, resp. Eight patients with Mallory bodies still showed fatty changes and 1 showed portal fibrosis without steatosis. Repeat biopsies from 42 patients without Mallory bodies revealed 2 cases of cirrhosis and 5 of portal fibrosis; most biopsies (35) still showed fatty change. It is concluded that Mallory bodies and alcoholic hepatitis give rise to development of connective tissue in the parenchyma and are a common cause for development of cirrhosis in alcoholics with fatty change of the liver.

8038 THE HEPATIC ARTERY IN CIRRHOSIS: AN ANGIOGRAPHIC PATHOPHYSIOLOGIC CORRELATION.

(E.) Rosenberg, R. F.; Sprayregen, S. (Montefiore Hosp., Bronx, N.Y.). *Angiology* 25(8):499-503, 1974.

The retrograde flow of contrast material to the pancreaticoduodenal, gastroduodenal, hepatic, and splenic arteries was examined in superior mesenteric arteriograms of 50 normal and 37 cirrhotic patients. Of the 50 control subjects, 9 showed no evidence of reflux; 8 showed reflux to the hepatic artery, 17 to the gastroduodenal artery, and 41 to the pancreaticoduodenal arcade. Of the 37 cirrhotic patients, 2 showed no evidence of reflux; 17 showed reflux to the hepatic and 5 to the splenic arteries, 25 to the gastroduodenal artery, and 35 to the pancreaticoduodenal arcade. These data offer angiographic evidence of increased hepatic arterial blood flow in cirrhosis. Pathologic and physiologic evidence of increased hepatic arterial blood supply include increased diameter of the hepatic arteries, increases in the size and number of intrahepatic arteries, and evidence that regenerating lobules of cirrhosis are supplied primarily by arterial blood, as is the connective tissue of the fibrous septa. In cirrhosis the portal vein becomes the major efferent pathway while the hepatic artery supplies most of the blood to the liver. Because of the increased arterial demand on the hepatic artery in cirrhosis, the artery is enlarged and collateral arterial circulation is manifested by the retrograde flow through the pancreaticoduodenal arcade, frequently as far as the hepatic and splenic arteries, on superior mesenteric artery injection. A pronounced accumulation of contrast within the liver parenchyma may be seen, indicating that the hepatic artery has essentially taken over the blood supply to the liver. It is suggested that the increased arterial blood flow contributes to the tortuosity of the intra-hepatic arteries frequently noted in cirrhosis. Celiac stenosis may be due in part to the collateral blood supply; ascites or upward retraction of the liver may accentuate or bring out celiac stenosis. Angiographic evidence corraborating this suggestion is the filling of the splenic artery in 5 of the cirrhotic patients but in none of the controls in the present series.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

8048 PRIMARY CARCINOMA OF THE GALLBLADDER. *(E.)* Beltz, W. R.; Condon, R. E. (Duke Univ. Med. Ctr., Durham, N.C.). *Ann. Surg.* 180(2):180-184, 1974.

The clinical records of 117 patients (89 women and 28 men, mean age 67 yr) with histologically proven carcinoma of the gallbladder were reviewed. The most frequent preoperative diagnoses were cholelithiasis in early cases and pancreatic carcinoma in more advanced cases. A correct preoperative diagnosis was made in only 11 instances. The majority of atients (71) presented with advanced disease with xtension and metastasis to the liver and to lymph odes along the common bile duct. The mean survival f this group, in whom no attempt was made at palliative or definitive therapy, was 8.5 weeks. In another group of 28 patients, palliative procedures ere performed after initial exploration demonstratd disseminated carcinoma. The mean survival was 5.4 weeks. Four patients had localized disease reognized at operation; 2 were treated with cholecysectomy and 2 with cholecystectomy and hepatic reection. The mean survival of these 4 patients was 4.7 months. There were 14 patients with clinically napparent carcinoma at cholecystectomy; the diagnois was established postoperatively by histologic xamination of the excised gallbladder. Two of the 4 patients survived more than 5 years; both surviors had early papillary carcinoma confined to the allbladder wall. The remaining patients with inpparent carcinoma died within 3 yr of recurrent arcinoma. Extended resection, while not of proven alue, might improve the survival of patients with ocalized carcinomas of the gallbladder. More localized and clinically inapparent carcinomas might e diagnosed if every gallbladder removed from older patients were examined by the surgeon in the operating room prior to completion of the operation.

8049 RECURRENT PYOGENIC CHOLANGITIS IN CHILDREN. *(E.)* Yue, P. C. K. (Dept. Surg., Univ. Hong Kong). *Aust. NZ J. Surg.* 44(1):53-57, 1974.

Recurrent pyogenic cholangitis mainly affects Chinese adults in Hong Kong but was encountered in 6 children (4 boys and 2 girls, aged 7-14 yr) seen over a 20-yr period. While all the children presented with abdominal pain and 5 had fever, jaundice was detected clinically in only 3. All 6 patients had hyperbilirubinemia as well as elevated serum alkaline phosphatase and polymorphonuclear leukocytosis. Only 1 patient showed a slight rise in SGOT and SGPT. The infective enteric bacteria were *Escherichia coli*, *Streptococcus faecalis*, and *Paracolon*. Emergency surgery revealed obstruction of the common bile duct in 5 patients and obstruction of the common hepatic duct in 1; in all cases the obstruction was caused by soft pigment stones. In 1 case, 2 dead ascaris worms were also present. Operative cholangiography was helpful in locating obstructions and residual stones. Surgical procedures included stone removal and T-tube choledochostomy in 3 patients and cholecystectomy plus internal drainage (side-to-side supraduodenal choledochoduodenostomy or transduodenal choledochoduodenostomy) in 3. All patients recovered rapidly and were discharged about 2 weeks later. Two patients required 2nd operations: 1 due to another attack of disease and 1 because of migration of an ascaris worm up the bile duct. In the latter, retrograde cholangiography 3 weeks later showed further migration of ascaris into the hepatic duct. Two other patients have been free from further attacks while 2 have had 1 mild attack of pain and fever, due, resp., to a residual stone in the left intrahepatic duct and a stricture at the confluence of the right and left intrahepatic ducts.

8050 CHOLECYSTOKININ CHOLECYSTOGRAPHY IN THE DIFFERENTIAL DIAGNOSIS OF ACALCULOUS GALLBLADDER DISEASE. *(E.)* Goldstein, F.; Grunt, R.; Margulies, M. (Lankenau Hosp., Philadelphia, Pa.). *Am. J. Dig. Dis.* 19(9):835-849, 1974.

A total of 42 patients with acalculous biliary tract disease were studied by cholecystokinin (CCK) cholecystography over a 13-yr period. Based on their response to CCK, 28 patients were classified as having cystic duct syndrome; 8, sphincter spasm or stenosis; and 6, hypercontraction of the gallbladder. Compared with 17 normal controls, patients with cystic duct syndrome showed marked impairment of gallbladder emptying and minimal, if any, filling of bile ducts. Patients with partial obstruction at the sphincter of Oddi also showed impaired gallbladder emptying; but their common duct became prominent, dye refluxed into hepatic ducts, and no dye entered the duodenum. Sphincter spasm (5 cases) could be differentiated from sphincter stenosis by the response to nitrates and/or anticholinergics. Patients with hypercontraction after CCK showed over 80% emptying of the gallbladder, usually within 5 min. Findings in this group were consistent with diagnosis of hyperplastic cholecystosis. All abnormal CCK responses were associated with reproduction of biliary tract pain. Treatment based on CCK cholecystography was successful for a majority of patients, with follow-up information ranging from 6 months to 11 yr. Attempts to correlate the type of biliary tract motor disturbance with histologic features of resected gallbladders and cystic ducts revealed a substantial overlap, ranging from normal gallbladder and cystic duct histology through varying degrees of chronic cholecystitis and cholecystoses to varying degrees of cystic duct inflammation and fibrosis. The overlapping histological features suggest shared etiologic factors.

8051 CLINICAL EVALUATION OF CHOLEDOCHODUODENOSTOMY. *(Rus.)* Sitenko, V. M.; Nechai, A. I.; Drobot, V. T.; Stukalov, V. V.; Gorkovoi, V. B. (S.M. Kirov Military Med. Acad., Leningrad, USSR). *Vestn. Khir.* 112(1):34-40, 1974.

Enterobiliary anastomoses were evaluated in 136 patients who had undergone choledochoduodenostomy and 4 who had undergone choledochojejunostomy for nonmalignant diseases of the biliary tract. Indications for anastomoses included stenosis of the terminal part of the bile duct (69 cases), suspected choledocholithiasis (51), cysts of the bile ducts (2), insufficiency of the sphincter of Oddi (2), chronic indurative pancreatitis (15), and bits of chitin membrane remaining in the bile ducts after rupture of a hydatid cyst (1). The possibility was investigated that cholangitis may be caused by discharge of duodenum contents into the bile ducts. X-ray examination of the anastomosis in 67 choledochoduodenostomies failed to reveal any signs of cholangitis, but anastomotic stenosis was observed. Of 115 patients with choledochoduodenostomies, 6 had recurrent cholangitis from 6 months to several years after surgery with no subsequent recurrence. Four cases of recurrent cholangitis were not related to anastomotic stenosis. Not a single case had anastomotic stenosis severe enough to cause a complete obstruction. The observations indicate that cholangitis following choledochoduodenostomy is not related to anastomotic stenosis.

8052 BILIARY TRACT EXCRETION OF CEFAZOLIN, CEPHALOTHIN, AND CEPHALORIDINE IN THE PRESENCE OF BILIARY TRACT DISEASE. *(E.)* Ratzan, K. R.; Ruiz, C.; Irvin, III, G. L. (Univ. Miami Sch. Med., Fla.). *Antimicrob. Agents Chemother.* 6(4): 426-431, 1974.

The biliary tract excretion of 3 cephalosporins, cefazolin, cephaloridine, and cephalothin, was compared in patients with biliary tract disease. In 1 group of 15 patients undergoing cholecystectomy for cholelithiasis or a nonfunctioning gallbladder, 1 of the 3 compounds was administered i.m. or i.v. at time of induction of anesthesia. In the absence of obstruction, mean antibiotic levels in bile from gallbladder and common duct were higher for cefazolin (17 and 31 μg/ml, resp.) than for cephaloridine (7 and 9 μg/ml) or cephalothin (1 and 4 μg/ml). Biliary tract levels generally paralleled serum levels. In 3 patients with severe cholelithiasis and/or obstruction of the cystic duct, the cephalosporin level in gallbladder bile was below 1 μg/ml despite common duct levels well above this amount. Eight patients with T-tube drainage were given 1 g of each of the 3 different cephalosporins on separate days. Cephaloridine was administered i.m., cephalothin i.v., and cefazolin both i.v. and i.m. Cefazolin concentrations in bile were many-fold higher than cephaloridine or cepalothin concentrations. Peak cefazolin levels in T-tube bile averaged 51 μg/ml after i.v. and 26 μg/ml after i.m. administration, whereas mean peak levels of cephalothin and cephaloridine were only 6 and 16 μg/ml, resp. T-tube levels reflected serum concentrations and obstruction to biliary flow impaired excretion of each of the drugs in 2 patients. In the absence of obstruction to bile flow, cefazolin is a logical 1st choice for therapy of a biliary tract infection.

GENERAL

8074 CONVERSION OF LONG-CHAIN UNSATURATED FATTY ACIDS TO HYDROXY ACIDS BY HUMAN INTESTINAL BACTERIA. *(E.)* Pearson, J. R.; Wiggins, H. S.; Drasar, B. S. (Central Middlesex Hosp., London, England). *J. Med. Microbiol.* 7(2):265-275, 1974.

Bacteria isolated from the feces of normal human subjects and from patients with high and low fecal hydroxystearic acid levels were screened for their ability to produce hydroxystearic acid from oleic acid, an unsaturated fatty acid. Fatty acid products were identified by several methods including thin-layer and gas-liquid chromatography using purified standards for comparison. Of 104 strains from normal subjects and 103 strains from 20 fecal samples from 15 patients with various gastrointestinal disorders, 94 strains could convert oleic acid to hydroxystearic acid. The most active strain was the enterococci; 98% were converters, most with moderate or high activity. Some active strains were also found among *Bacteroides* (18%), bifidobacteria (32%), clostridia (50%) and enterobacteria (21%). Five of 6 oleic acid-hydrating bacteria studied could also hydroxylate palmitoleic but not linoleic acid. No relation was demonstrated between fecal hydroxystearic acid level and the number of bacteria in the feces able to produce this acid.

8075 CELLULAR IMMUNITY, PERIPHERAL BLOOD LYMPHOCYTE COUNT AND PATHOLOGICAL STAGING OF TUMOURS IN THE GASTROINTESTINAL TRACT. *(E.)* Bone, G.; Lauder, I. (Dept. Surg., Univ. Newcastle upon Tyne, England). *Br. J. Cancer* 30(3):215-221, 1974.

The peripheral blood lymphocyte count was measured in 72 controls and in 74 patients with histologically proven carcinoma of the gastrointestinal tract. The count was correlated with the pathological stage of tumor spread and the patient's delayed hypersensitivity response to 2.4 dinitrochlorobenzene as determined by skin patch testing. A statistically significant correlation was found between the peripheral blood lymphocyte count and the response to 2.4 dinitrochlorobenzene. There was a linear association between the extent of spread of the tumors and the lymphocyte count. Those patients with low peripheral blood lymphocyte counts tended to have more advanced tumors and a poor response to 2.4 dinitrochlorobenzene. Possible causes of this lymphopenia included: 1) increasing tumor mass; 2) thymic atrophy secondary to high circulating corticosteroid levels due to stress; 3) extensive involvement of bone marrow and/or lymph nodes by tumor; 4) release of toxins or free antigen from tumor cells; and 5) migration of sensitized lymphocytes into the neoplasm with attachment to tumor cells.

GENERAL

Parasitology

8124 IMMUNITY TO INTESTINAL TAPEWORMS: THE REJECTION OF Hymenolepis citelli BY MICE. *(E.)* Hopkins, C. A.; Stallard, H. E. (Wellcome Labs. Exp. Parasitol., Univ. Glasgow, Bearsden, Scotland). *Parasitology* 69(1):63-76, 1974.

Hymenolepis citelli cysticeroids were administered by stomach tube to male CFLP mice aged 40-45 days. Beginning the day after infection, some mice were injected 3 times/week for 1 week with cortisone acetate (1 mg, i.m.). Approximately 90% of the cysticercoids became established, equally high recovery rates being obtained after the administration of 1, 3, and 6 worms. In mice infected with 1 worm, the worms increased in weight until day 25-28 postinfection. After a few days at maximum weight (about 24-42 mg), there was a 10-25% decrease in weight, followed by stabilization up through day 90. None of the worms were lost before day 30, after which small losses were observed; only in 2 experiments with older mice (7 weeks) did losses exceed 50% by day 80. In mice infected with 3 worms, 50-80% of the worms were lost between days 17 and 30, while in mice infected with 6 worms, 75% or more of the worms were lost between days 17 and 22. In mice infected with 3 or 6 worms, a residual infection, usually consisting of one worm, persisted in 20-50% of the mice throughout the 63-78-day experiment. In mice infected with 3 or 6 worms, cortisone prevented worm loss, and the worms grew at the same rate as in the single worm infections. The worm burden/mouse remained constant from day 25-55 in the cortisone-treated animals. The results suggest that the immune response apparently elicited by *H. citelli* in the host is a vital factor in regulating the number and longevity of these worms (and probably other tapeworms) in the gut of some natural hosts.

8125 GIARDIASIS IN AMERICAN TRAVELERS TO THE SOVIET UNION. *(E.)* Brodsky, R. E.; Spencer, Jr., H. C.; Schultz, M. G. (Ctr. Dis. Control, Atlanta, Ga.). *J. Infect. Dis.* 130(3):319-323, 1974.

Data collected from questionnaires answered by 1419 American travelers to the Soviet Union since 1969 was analyzed with respect to the incidence of giardiasis. Of these patients, 502 (35.5%) were ill either during their tour or shortly after their return. Stool examinations were reported for 153 patients, with 83 (54%) being positive for cysts of *G. lamblia*. Of all patients studied, 324 had documented giardiasis based on positive stools and/or diarrheal illness lasting for 1 week or longer. There was no correlation between health precautions or dietary restrictions and the incidence of giardiasis. Tap water was considered to be the likely source of infection.

GENERAL

Regional Enteritis

8137 GRANULOMATOUS ENTEROCOLITIS IN CHILDHOOD AND ADOLESCENCE. *(E.)* Guttman, F. M. (St. Justine Hosp. Children, Montreal, Canada). *J. Pediatr. Surg.* 9(1):115-122, 1974.

Granulomatous enterocolitis was studied in 52 children and adolescents (27 males and 25 females, aged 2.5-27 yr) over periods of 1-24 yr. Granulomatous ileocolitis was present in 12 patients, ileitis and jejunitis in 8, and terminal ileitis in 32. The earliest onset of symptoms began at 2 1/2 yr and 32 subjects experienced onset of symptoms before the age of 15 yr. Abdominal pain was the most frequent symptom (43 cases), followed by fever of unknown origin (27), diarrhea (20), weight loss (14), anorectal inflammation, and failure to grow (6). Of the patients with growth retardation, 3 were left permanently stunted. One child stopped growing at 8 yr but showed no symptoms of Crohn's disease until he was 13 yr old. After surgery, he grew 4 inches; 2 other patients also had growth spurts following operations. Although surgery *per se* did not stimulate growth, it offered a period of respite from the disease to allow for growth, and, in a low but respectable percentage of cases, a long-term abeyance of symptoms. Seventeen of 33 patients on medical management were doing well upon follow-up 1-20 yr after treatment initiation. The rest often had recurrent symptoms for many years and were on therapy intermittently. Of the 19 patients who underwent surgery, 12 had dramatic remissions. Appendectomy after acute illness was followed by remission in only 3 of 15 patients; 7 of these required another operation and 4 others had several hospitalizations with recurrent disease. The recurrence rate after operation was 36.8% while the rate of a 2nd operation was 21%.

8138 SHORT-TERM COURSE AND PROGNOSIS OF CROHN'S DISEASE. *(E.)* de Dombal, F. T.; Burton, I. L.; Clamp, S. E.; Goligher, J. C. (Gen. Infirm., Leeds, England). *Gut* 15(6):435-443, 1974.

Records of 322 patients (161 men and 171 women, aged 9-70+ yr) with Crohn's disease treated over a 30-yr period were analyzed to determine the course and outcome of the initial referred attack. Only 17 of the 322 patients (5.1%) obtained complete remission of symptoms with conservative treatment. In another 75 patients (22.8%), conservative management was partially successful; symptoms persisted but were not incapacitating. In 10 patients (3%), severe symptoms persisted for over 1 yr, and this resulted in reclassification to chronic continuous disease. When patients were grouped according to site of disease, 11.4% of 70 patients with disease restricted to the large intestine achieved full remission on conservative management. This was in contrast to 5.9% of 136 patients with disease confined to the small intestine and 0.9% of 115 patients with diffuse disease affecting both the small and large intestine. Minor surgery was performed on 25 patients with no fatalities, while major surgery on 199 patients resulted in 10 deaths. Including 1 medical death, the overall death rate was 3.3% and this was affected chiefly by the severity of the attack and the age of the patient. The severity of the attack was classified as mild, moderate, or severe depending upon bowel habit, rectal bleeding, abdominal pain, pulse rate, temperature, hemoglobin level, and weight. No deaths occurred in mild attacks while the death rate in severe attacks was 8.8%. While no patient under 20 yr died, the death rate in patients over 60 yr was 14.8%. Comparison with an earlier series of 204 patients with ulcerative colitis showed considerable differences in the course and prognosis of the 2 diseases. In particular, 70% of the patients with ulcerative colitis achieved remission on conservative management, compared with only 5.1% of the patients with Crohn's disease. Moreover, the rate of recourse to radical surgery was far higher in Crohn's disease (56.9%) than in ulcerative colitis (11.3%). Differences in the short term course of these 2 conditions cannot be attributed to the differences in age or extent of the disease.

8139 HYPERALIMENTATION AS PREPARATION FOR SURGERY IN TRANSMURAL COLITIS (CROHN'S DISEASE). *(E.)* Eisenberg, H. W.; Turnbull, Jr., R. B.; Weakley, F. L. (Cleveland Clin. Fdn., Ohio). *Dis. Colon Rectum* 17(4):469-475, 1974.

Forty-six high-risk patients with histologically proven Crohn's disease of the ileum and/or colon received hyperalimentation for periods of 5-46 days prior to or following surgery. All 25 patients who received preoperative hyperalimentation gained weight (average of 0.34 kg/day). There were no deaths, very few postoperative complications, and all but one incision healed promptly. Only 2 of 12 patients who received postoperative hyperalimentation failed to gain weight; both had intra-abdominal sepsis. The most frequent indication for postoperative hyperalimentation was intestinal obstruction. Fistulas in 5 of 18 patients with chronic, draining defects closed spontaneously while the patient was sustained by hyperalimentation. Hyperalimentation also played a crucial role in the management of intestinal obstruction, toxic megacolon, and short bowel syndrome. One patient each developed gram positive sepsis, hemothorax, pancreatitis, and catheter-fragment embolus. Two patients each developed postoperative seizures and hyperosmotic, nonketotic acidosis, and several had hypophosphatemia, usually without symptoms.

8140 ASCORBIC ACID DEFICIENCY AND FISTULA FORMATION IN REGIONAL ENTERITIS. *(E.)* Gerson, C. D.; Fabry, E. M. (Mount Sinai Sch. Med., City Univ. New York, N.Y.). *Gastroenterology* 67(3):428-433, 1974.

Ascorbic acid measured in leukocytes and platelets, and in serum, was significantly decreased in 40 patients with regional enteritis compared to 32 normal subjects. This was related, at least in part, to low intake of ascorbate in patients with regional enteritis. Patients taking supplemental vitamin C had normal leukocyte ascorbic acid, while serum ascorbic acid remained low. Ascorbate concentration was measured in homogenates of ileal tissue obtained at ileal resection performed on 20 ileitis and 8 nonileitis patients, and there was an excellent correlation with leukocyte ascorbic acid. Patients with ileitis and fistulous tracts were noted to have significantly lower ileal and blood ascorbate levels than patients without fistulae. It is suggested that fistula formation in ileitis may be related in part to local ascorbate deficiency.

8141 CROHN'S DISEASE IN HETEROTOPIC GASTRIC MUCOSA IN A MECKEL'S DIVERTICULUM. *(E.)* Bondeson, L.; Starck-Bondeson, A. G. (Malmo Gen. Hosp., Sweden). *Acta Pathol. Microbiol. Scand.* [*A*] 82(3):427-430, 1974.
